SIR,—I was one of those fortunate members of the medical profession who was able to accept the invitation to spend last week-end in Harrogate, when, besides being royally entertained, we were given opportunities of visiting and having explained to us the working of the Royal Bath Hospital and the Royal Baths and Wells. I would like to call attention to one lesson which the visit should have impressed on the medical visitors—namely, the vast amount of benefit to the sick which results from appropriate general non-specific treatment skilfully applied.

The growth of bacteriology, the development of clinical pathology and biochemistry have tended to divert the medical profession's mind from general to specific therapeutics. Vaccines and serums have enabled us to deal very effectively with certain diseases, and these advances in scientific knowledge are not neglected by the Harrogate physicians; but in the main the Harrogate treatment is general treatment, having for its aim the full development of the natural defences of the body by the stimulation of metabolism and the removal of injurious waste products. That this line of treatment may be very successful the patients shown to us in the hospital clearly showed.

A distinct advance in the study of that form of general treatment classed as hydrological has been made by the University of London by inaugurating a course of lectures and demonstrations on this subject—an advance for which we have to thank in the first instance Dr. Fortescue Fox, Dr. Campbell McClure, and their co-workers, but so apathetic had the profession previously been to this question that it permitted without protest the scrapping of all the balneological apparatus of the institute for officers in Great Portland Street soon after the end of the war, and it seems probable that a similar department of a large hospital for pensioners will be treated in the same way unless prompt measures are taken to prevent it. Much is said about the failure of panel practitioners to treat their cases, while at the same time an excellent method of treatment is not made available to them.—I am, etc.,

London, W., July 2nd.

HAROLD H. SANGUINETTI.

#### THE PEPTONE TREATMENT OF ASTHMA.

SIR,—In answer to a letter published recently in your columns (June 30th, p. 1116) by Dr. Auld, I must apologize for any inaccuracy that occurs in my book on asthma with regard to the dosage of peptone advised by Dr. Auld for intravenous injection. What I meant to convey was that he used a mixture of both Witte's and Armour's peptones, while others used Witte's alone. The word "mixture" should be read instead of the word "each" in the text.

With regard to the absence of notes of reference to Dr. Auld's many articles, I imagined that his work on this subject was so well known as to need little further reference from me.—I am, etc.,

London, W., July 6th.

FRANK COKE.

decrease as in cases of dementia praecox. Synchrony were somewhat of atrophy and the cells showed in some cases a certain amount of atrophy and vacuolation; slight nuclear pro-literation was present in a few of these cases. A few cases of tuberculous showed atrophy of the cells and vacuolation of normal appearance. A few of the specimens presented a slight atrophy of the cells and vacuolation of their cytoplasm, but in most of them no definite cell changes were observed comparable with those seen in dementia praecox.

(b) *Fibrosis*.—There seemed to be a certain amount of fibrosis in all the dementia praecox cases, and this was also seen, though to a slighter extent, in some of the other psychoses. This fibrous hyperplasia was sometimes coarse and consisted of heavy wavy bundles which extended round groups of cells. On the other hand, it was in many cases a very fine fibrosis and delicate strands of fibrous tissue ramified between individual cells. In one dementia praecox case there were such thick bands of organized fibrous tissue that they could even be seen in sections by the aid of a hand lens. In a few of these cases the media consisted of little else but fibrous tissue, and the amount of cellular tissue was very small. It could not be said it was this fibrosis alone that caused the cell changes, for in some adrenals that showed a marked fibrosis the cells were fairly normal. General paralytic cases showed a fair amount of fibrosis, but there was no peculiar arrangement of the fibres. The majority of the hospital and tuberculous cases showed no fibrous hyperplasia, though there were a few specimens in which this was present.

(c) *Nuclear Ratio*.—It was thought that as there were in some cases such numbers of nuclei and so few cells, it might be instructive to count the numbers of nuclei and of cells in a given area. This was done, the area used being 0.25 mm. The number of nuclei and of cells were separately counted in three such areas and the averages taken. The number of nuclei was divided by the number of cells and a ratio of nuclei to cells was obtained. The averages of the nuclear ratio in the different classes of case were as follows:

|                   |     |     |     |     |                |
|-------------------|-----|-----|-----|-----|----------------|
| Dementia praecox  | ... | ... | ... | ... | 6.37 to a cell |
| Other psychoses   | ... | ... | ... | ... | 3.82           |
| General paralytic | ... | ... | ... | ... | 1.65           |
| Hospital cases    | ... | ... | ... | ... | 1.91           |
| Tuberculous       | ... | ... | ... | ... | 1.84           |

A glance at the above figures shows that the hospital, the tuberculous, and the general paralytic cases have an almost identical average ratio. The dementia praecox cases show by far the highest ratio of all. The other psychoses occupy a place midway between the others, and it would seem as though this were possibly a stage of the process towards what is found in the dementia praecox cases.

(d) *Lymphocytosis*.—In many of the general paralytic cases a lymphocytosis was present along the line of the fibrous septa of the medulla and the cortex. This was very marked in some of the cases where the lymphocytes formed clumps which could be well seen even under a low power magnification. Some of the adrenals showed this much more markedly than others, and even in those cases where it was very marked the glands seemed to be otherwise practically normal.

(e) *Lipoid*.—In the great majority of cases this was present in small amounts in the medulla. It was distributed in an often in quite a small proportion of them. It was absent, as in the cortex, in cases where there was an acute or chronic septic condition.

**SUMMARY OF DISTINCTIVE CHANGES WHICH CHARACTERIZE THE DIFFERENT CLASSES OF CASE.**  
*Dementia Praecox.*  
Much more striking changes were found in this class of case than in any other, and these will now be given seriatim. (a) *Size*.—The organs were smaller than the normal; this was quite apparent to the naked eye, and very marked in the shrunken appearance which was as a rule quite typical. (b) *Weight*.—As a rule the organs were much lighter than the normal and many of them weighed only from 2.8 to 2.9 grams.

5 grams. The average weight was somewhat higher than this, but it has been already shown why this was so. (c) *Medulla as a Whole*.—This was distinctly narrowed and in some cases was a mere narrow strip of tissue. In a few cases the medulla was as wide or wider than the normal, but this may be accounted for by the fact that in these cases there was marked fibrous hyperplasia and only comparatively few normal medullary cells. In one of the cases the fibrous bands were so thick that they could just be seen by the naked eye.

(d) *Medullary Cells and Nuclei*.—The cells were smaller than the normal and their cytoplasm much vacuolated. In some cases even atrophic cells were very few in number. The nuclei were, relatively to the normal, smaller and paler, the chromatin granules were fewer and finer, and the chromatin in general was simple or indistinct. They varied much in shape and size, and were usually out of proportion to the size of the cell. There were many nuclei present which were not surrounded by cytoplasm, and these were pale and larger than those which were surrounded by cytoplasm; they were generally oval or fusiform in shape, and the granules were scanty and fine. The ratio of nuclei to each cell (this had previously been explained) was 6.37, while the normal was 1.91.

(e) *Fibrous Tissue*.—Medullary hyperplasia has already been very fully described; it varied enormously. In some cases slight, and in others there was great coarsening of the fibrous framework; it may be a very fine proliferative ramification, or there may be thick organized strands of fibrous tissue.

(f) *Cortex*.—Here little or no change was observed, except that in some cases the fibrous septa were much thickened. Where there was fibrosis in the medullary portion it was not observed that there was always a corresponding thickening of the fibrous septa of the cortex. Lipoid was absent only in cases dying of acute or chronic septic conditions.

#### Other Psychoses.

In manic-depressive cases changes very similar to those in early cases of dementia praecox were seen in some of the cases. The cells were in some cases smaller, the nuclei immature, the cytoplasm was vacuolated, and a slight fibrosis was sometimes present. In no cases were the changes very advanced. The ratio of nuclei in the medulla was high—3.82 to a cell—which is midway between the ratio of the normal and dementia praecox cases.

#### General Paralysis.

The adrenals of these cases were larger than the normal, and there were few exceptions to this; this was very noticeable even on naked-eye examination of the slide preparation, and the average weight was greater. The medulla in all cases was large and wide, and here fibrosis was occasionally present, but never to any great extent. The cells were normal or practically normal throughout, and contained a great number of granules and a complicated chromatin skein. In some cases there was slight vacuolation of the cytoplasm, and in a few of the cases synchia were present. The nuclear ratio corresponded with that of the normal adrenals.

The most marked feature was the presence of lymphocytic infiltration may to some extent account for the weight of the adrenals in this disease even exceeding the average of the normal. But we are quite sure that this does not wholly account for the large adrenal glands in general paralytic cases. More probable is it that the large glands are connected with a strong sexual instinct. Sprochlaetes were not seen; they have been present. It is probable that these lymphocytes came from the cerebro-spinal fluid.

#### Tuberculous Cases.

There was nothing remarkable to note about most of these cases, as they did not differ from the normal except in their cortical lipid content. Sometimes the

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a meeting of Fellows on July 5th five Fellows were elected into the Council in the vacancies occasioned by the retirement in rotation of Sir Charters J. Symonds and Sir Herbert F. Waterhouse, by the deaths of Sir William Thorburn and Sir Charles Ryall, and by the resignation of Mr. F. F. Burghard. In all 1,052 Fellows voted, 1,043 sending their ballot papers through the post and 9 voting in person, and the result of the poll was as follows:

|                                           | Votes. | Plumpers. |
|-------------------------------------------|--------|-----------|
| JAMES BERRY ... ..                        | 612    | 6         |
| GEORGE ERNEST GASH, C.M.G., D.S.O. ... .. | 466    | 28        |
| JOHN HERBERT FISHER ... ..                | 445    | 53        |
| PERCY SARGENT, C.M.G., D.S.O. ... ..      | 445    | 3         |
| WILLIAM SAMPSON HANDLEY ... ..            | 433    | 8         |
| Sir H. F. Waterhouse ... ..               | 358    | 4         |
| Herbert J. Paterson, C.B.E. ... ..        | 342    | 11        |
| George Grey Turner ... ..                 | 332    | 13        |
| Victor Bonney ... ..                      | 304    | 3         |
| Thomas Percy Legg, C.M.G. ... ..          | 177    | 4         |
| Donald Armour, C.M.G. ... ..              | 111    | 6         |

Mr. Handley becomes substitute member of Council for Mr. Burghard until July, 1929, and Mr. Sargent becomes substitute member of Council for Sir William Thorburn until July, 1930.

## CONJOINT BOARD IN IRELAND.

The following candidates have passed the Final examinations:

Jane A. Brennan, F. S. Bourke, H. Bugler, P. J. Clarke, S. B. Carlisle, Dorothy M. Coulson, S. L. Christie, S. H. Ervin, F. B. Harrison, P. Kilcoyne, P. S. McCabe, P. J. O. MacDonnell, Iris P. Nolis, T. V. C. Nolan, Mary R. Nolan, D. M. F. O'Connor, J. F. O'Connor, Anne O'Connor, A. T. O'Grady, C. B. D. O'Honaghan, Helen P. Regan, Mary A. Ryan, J. D. Sayers, R. E. Sadlier, S. L. Simon.

## Obituary.

PATRICK WHYTE RATTRAY, M.A., M.B. ABERD.,  
F.R.C.S. Eng.,  
Holloway.

THE death of Dr. Patrick Whyte Rattray on July 2nd, his 64th year, of angina pectoris, removes one who was regarded by his fellows as no ordinary man. A graduate of the highest distinction both in arts and medicine of the University of Aberdeen, he was for a time senior demonstrator of anatomy there.

Dr. A. Blackhall Morison writes: "Those of his contemporaries who survive, will recall the high reputation he had as a teacher. Some years ago, the writer of this notice invited a well known Aberdonian to dinner, and remarked that he had also asked one of the most distinguished graduates Aberdeen ever sent out to meet him, who was living contentedly in general practice. He at once inquired, 'Do you mean Pat Rattray?'"

Rattray appears to have sought teaching appointments in anatomy and the assistant surgeoncy to a hospital in earlier life, and on all these occasions unsuccessfully, after which he quietly betook himself to general practice, which he cultivated with success. The writer, who was occasionally invited to confer with him, always regarded it as a compliment, and usually remarked on meeting him, "What insoluble conundrum have you set me this time?" For, the cases in which Rattray sought counsel, were always "hard nuts to crack." When he failed in his efforts to secure the public appointments referred to (and who can foretell the issue of such contests?) he seems to have shunned all publicity. He wrote nothing, which is to be regretted, for the studies of one with his calm judgement and comprehensive outlook would have been valuable. It is no abuse of language to state that, silent and unobtrusive as was the career he chose, one word alone adequately describes him—he was "great," and we shall not often look upon his equal.

He leaves a widow, a son (who did good work in the naval flying corps during the war), a daughter, and warm friends to mourn his loss.

DONALD MURRAY, M.B., C.M. GLASGOW,  
Formerly M.P. for the Western Isles.

WE regret to announce the death of Dr. Donald Murray, which took place in a London nursing home on July 6th, in his 60th year. Dr. Murray was born at Stornoway, and received his medical education at Glasgow University,

where he graduated M.B., C.M. in 1890. He was keenly interested in politics even as a student in Glasgow, and was president of the University Liberal Club in 1889; he was president also of the Medico-Chirurgical Society in 1890. For some years he was in practice at Brora, Sutherlandshire, and later at his native town of Stornoway. In 1910 he took the D.P.H. of Aberdeen University, and was subsequently appointed medical officer of health for the island of Lewis and the burgh of Stornoway, and school medical officer for Lewis and the western portion of Ross and Cromarty. From 1905 to 1910 he was chairman of Stornoway school board, and he was a justice of the peace for Ross and Cromarty. He resigned his offices on being elected to Parliament as an Independent Liberal in 1918. He soon made himself at home in the House of Commons and his ready wit enlivened many otherwise dull hours. He took an active part in the work of his party, and as a member of the Parliamentary medical group. He was an old member of the British Medical Association, and was always ready to aid the Association in its parliamentary work. He was defeated at the general election in 1922 by a National Liberal; his defeat was rather a severe blow to him and he had hoped soon to return to Westminster for a Highland constituency. He had a passionate love for the Highlands and for his native island, and while a member of the House of Commons endeavoured to improve the lot of the crofters in his constituency.

His funeral took place on July 9th, at Stornoway, and a memorial service was held at Highgate Presbyterian Church, London, when Sir Donald Maclean gave a brief address, speaking of Dr. Murray's high ideals, courage, independence, and friendship. He was faithful in all things, tender as a woman. They went through hard times together, but he never failed in his loyalty to his ideals, his courage, his independence of opinion, and his sense of humour. He was no man's enemy, but he had a hatred of social injustice, no matter where, and to its remedies he devoted his life.

A. G. PARROTT, M.R.C.S., L.R.C.P.,  
Shanghai, China.

ON May 22nd, 1923, Dr. A. G. Parrott died suddenly from heart failure, at the age of 67, at his home in Shanghai, China. He was born in Suffolk and went out to China in 1878, and worked for six years in the China Inland Mission. In 1884 he returned to London with his wife and family and afterwards entered as a medical student at the London Hospital, and after six years' study he took the diplomas of M.R.C.S. and L.R.C.P. in 1892. He returned to China in 1893 to work with the Open Brethren as a medical missionary. He settled at Laohokou, a city in the north of Hupeh province, on the Han river, some thousand miles inland from Shanghai.

Life and medical work in a far-inland station in China in those days were by no means easy, and the stress and strain of it no doubt largely contributed to the illness and death of his first wife. As a consequence of the Boxer upheaval in 1900 Dr. Parrott had to leave Laohokou, and went to reside in Shanghai, engaging in private practice and throwing himself into all kinds of mission work.

He served as honorary medical officer to the Door of Hope Rescue Homes for Chinese girls, to the Foreign Women's Home, to the Blind School for Chinese boys, and to the Chinese Industrial School. He was visiting physician to the Shantung Road Hospital for Chinese.

Dr. Parrott was only indisposed for twelve days. Under rest and treatment he recovered sufficiently to sit up and enjoy reading, but his heart suddenly gave out and he died. He is survived by his widow and four out of his six children, to whom the deepest sympathy is extended.

Mr. Cecil J. Davenport, F.R.C.S., of Shanghai, to whom we are indebted for these particulars, adds: "He leaves behind him a fragrant memory, an inspiring example, and many sorrowing friends who feel that earth is poorer through the loss of his humble, helpful, hopeful presence."

FIG. 8.

SIR STEWART STOCKMAN, chief veterinary officer to the Ministry of Agriculture, has been elected president of the Royal College of Veterinary Surgeons.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 1st, at 7 p.m.

MESSRS. KNOEDLER AND CO., of 15, Old Bond Street, W., are exhibiting a collection of some fifty pictures by nineteenth-century French painters. At the back of the catalogue is a letter addressed to Sir Coutts Lindsay at the Grosvenor Gallery by a group of French artists, apparently at the end of last century. Many of these painters are now dead, but pictures by most of them are included in the present exhibition. The writers of the letter describe themselves as struggling against convention and routine to bring back art to the scrupulously exact observation of nature, attempting to render the reality of form in movement as well as the fugitive phenomena of light. The collection is of great interest in showing the development of art during the nineteenth century, from the landscapes of Corot with figures from the classical age and such pictures as Géricault's trumpeter of the Imperial Guard, to the realistic figures of Edouard Manet and Degaz and the landscapes of Claude Monet and Sisley. A portrait of Mlle. Gonin by Ingres can be compared with that of Mlle. Lemonnier by Manet. The method of producing effects with thick dabs of paint is shown in Monticelli's *Les Reiters*, and we may admire the iridescent haze of Monet's *Palais Ducal* at Venice. The designers of the exhibition seem to have accomplished their purpose, and the collection is well worth a visit, and the observer will be able to judge how far the writers of the letter to Sir Coutts Lindsay have attained the objects with which they set out.

PATRICK JOSEPH HONAN, aged 26, who graduated M.B., B.Ch., B.A.O. Belfast in 1920, was convicted at the Surrey Assizes on July 9th on the charge of performing an illegal operation upon a woman. According to the report in the *Yorkshire Post* he admitted misconduct with the woman and that he had performed the operation which led to miscarriage. He was sentenced to eighteen months' hard labour. The judge said that but for his character and comparative youth, and the fact that he did not commit the offence for gain, but from personal reasons, he would have sentenced him to a long term.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Nacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### INCOME TAX.

"IRISH SURGEON" inquires whether the cost of attending purely professional meetings can be claimed as expenses.

\* \* We are of opinion that the reply is in the negative, assuming, as we do, that the meetings in question are for the furtherance of general professional interests rather than in connexion with some particular professional work for which remuneration is being received.

"F. J. T." bought his partner's half-share in the practice in February, 1923. What is the correct basis of his liability for the financial year ending April 5th, 1924?

\* \* "F. J. T." is in the position of a successor in the practice to the old firm; as such he is liable to tax on the full profits of the practice on the three years' average, but can claim an adjustment of that assessment if he should find that the amount of his profits (not necessarily on the basis of cash receipts) for his first year as sole proprietor has been less than the sum assessed.

"W. A. M." inquires (a) as to allowance of subscriptions to British Medical Association and Medical Defence Association, (b) as to the basis of assessment of fees from the Ministry of Pensions (part time) and locumtenent work, and (c) whether he can make any claim for loss incurred in a practice he has purchased.

\* \* (a) The proportion expended on membership is allowable; we suggest as a minimum that £33s. might be taken in the former case as representing the cost of literature supplied to members. (b) Strictly each appointment is separately assessable under Sch. E on the basis of the current year's (or period's) receipts; we believe that in practice in such a case as "W. A. M.'s" the whole earnings are pooled as being income derived in the form of professional profits assessable under Sch. D on the three year's average, but there seems to be no statutory title to that form of assessment. (c) "W. A. M." is assessable on his predecessor's average, which he can have reduced to nil on showing that owing to some specific cause since or by reason of the succession his work has resulted in a financial loss; if he has other income for the same year the amount of the loss can be set against it, and repayment claimed if that income has borne tax, but if that be done the loss cannot be carried forward for future averages as a negative quantity.

### LETTERS, NOTES, ETC.

#### WIGHT, WHITE, LIGHT.

THE study of place-names is bewildering, and if we may judge from the scorn with which one learned writer greets the suggestions of another learned writer, not much progress has yet been made in establishing principles. It is perhaps because the British Medical Association is going to hold its annual meeting in Portsmouth, where the Isle of Wight lies across the narrow water, that "An Ignorant Student" has sent us a copy of a pamphlet on *Origins in Place Names*, luxuriously printed at the Chiswick Press. It suggests a generalization which may prove useful. In many place-names in England there is an element which indicates whiteness, and an explanation has been found in chalk cliffs or limestone formations. The suggestion now made is that the reference is not to whiteness but to lightness, a clearing or open space upon which the sun struck, relieving the gloom of the forest; it would be on such areas that our primitive ancestors would build their villages and cultivate the soil, and early feel the need of a name. The Romans called the Isle of Wight "Vectis," and Canon Taylor, still a respectable authority, was confident that Wight was derived from the Roman name according to phonetic laws, which, we believe, are still admitted. Taylor calls it a corruption, but it is more probable that the Romans corrupted an earlier name. It seems to be accepted that white is derived at long range from the Sanskrit "ceta," so that it does not seem altogether unreasonable to suggest that the name of the Isle before the Romans came was something like "Vit," with a long "i."

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 20.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 6  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 5 0  |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded. Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restants* letters addressed either in initials or numbers.

occurring in the biogenetic psychoses are the changes in the testes in cases of general paralysis due to local inflammation

affects the bile ducts, pancreatic duct, and duodenum simultaneously. In such cases there is probably a new growth of the papilla of Vater or the adjacent region, and a search should be made for cancer cells. (3) If there is retention of bile without pancreatic retention, cancer of the head of the pancreas is probably not present, but the bile ducts may be compressed directly by a stone or a primary new growth, or indirectly by enlarged glands or adhesions. (4) If there is complete pancreatic retention—that is, absence of trypsin and lipase without biliary retention (that is, presence of pigments and bile salts)—there is probably a new growth of the head of the pancreas involving Wirsung's duct, but not the common bile duct.

## 28. Intramuscular Injections of Sulphur in Chronic Arthritis.

H. HAYN (*Deut. med. Woch.*, May 25th, 1923, p. 684) gives a very favourable account of the treatment of chronic joint disease with intramuscular injections of sulphur in olive oil. The ingredients of the emulsion were pure sulphur 1 to 8, olive oil 80 to 100, and eukalyptol 20. He experienced considerable difficulty in keeping the higher concentrations of sulphur in suspension, and found it advisable to shake well and to warm the emulsion before injecting it. The actual dosage of sulphur is not recorded in each case. The results of the injections were remarkably uniform; twelve hours afterwards there was a rigor, the temperature sometimes rising to 40° C., and the patient complaining of severe headache and great pain in the joints most affected. There was also general lassitude, and at the site of the injection slight swelling with tenderness. In no case did necrosis or abscess formation ensue. The general reaction usually passed off in twenty-four hours, and never took longer than forty-eight hours to do so. The injections were repeated every fifth or sixth day, and there was never any sign of inflammation of the kidneys or of cardiac complications. The author gives details of six cases, and concludes that this treatment is symptomatically effective and palliative. It is not indicated in acute early cases, which are more suited to other treatment.

## 29. Treatment of Ichthyosis with Thyroid Extract.

MARIE KROGH and C. WITH (*Ugeskrift for Læger*, May 17th, 1923, p. 353) have investigated the basal metabolism in several cases of ichthyosis, and they have often found this disease to be associated with a reduction of the basal metabolism. By giving thyroid extract they have not only increased the basal metabolism, but they have in several cases effected marked improvement of the ichthyosis. They therefore confirm the views of earlier writers who have connected ichthyosis with hypofunction of the thyroid. They have not, however, been able to establish any definite relationship between the severity of the ichthyosis and the degree of the reduction of the basal metabolism. They add the warning that if the basal metabolism rises above normal under treatment with thyroid extract it should be discontinued.

## Surgery.

### 30. Meat and Fish Bones Impacted in the Oesophagus.

THOMAS GUTHRIE (*Journ. of Laryngol. and Otol.*, May, 1923, p. 229) considers that the number of fragments of meat and fish bone which become impacted must be only a small proportion of those swallowed. The human oesophagus is less tolerant of these splinters than that of the carnivora such as the dog, and any existing disease of the oesophagus makes impaction more probable. The author notes certain distinctive features in these cases of impacted bone: (1) The patient has only a history of pain after swallowing some food. He is usually unable to give any estimate of the size and shape of the body, as in the case of pins or tooth-plates. (2) The patients are often edentulous—making detection of bones difficult but oesophagoscopy easier. (3) Bones usually have organic matter adhering to them, and this rapidly undergoes decomposition, causing early inflammatory lesions in the oesophagus and surrounding structures. This of course makes removal more difficult and the condition more dangerous. (4) Bones are singled out from other foreign bodies for attempts to "push down" (a) by the patient by swallowing masses of bread or (b) by the medical attendant with bougie and probang. The latter attempts are definitely harmful and prejudice any oesophagoscopic treatment. (5) The pain of an impacted bone persists between attempts at swallowing, and is fairly accurately localized. The pain caused by a scratch of the mucosa may be considerable, but is seldom persistent. (6) X-ray examination should invariably be practised before attempts at removal. (7) Removal under direct vision is the only permissible form of treatment. The

author recommends the use of a general anaesthetic in all but exceptional cases. (8) Instrumentation must be extremely cautious owing to the inflammatory changes of the mucosa. THURSTAN HOLLAND (*Ibid.*) describes his x-ray technique. He gives opaque food with the left side of the patient's back against the screen. If a foreign body be present there may be complete obstruction, a hitch in the passage with or without some of the food being left behind, or occasionally the stream of food passes without a hitch but forks at some point and then reunites. This is due to a foreign body bridging across the oesophagus.

### 31. Lung Abscess.

J. HOMANS (*Boston Med. and Surg. Journ.*, April 19th, 1923, p. 577) discusses the etiology and clinical features of lung abscess occurring mainly as a post-operative accident, 13 out of 23 cases being due to this cause. The distribution of abscesses among the lobes is similar to that of other acute pulmonary infections, the right lung, and especially the right lower lobe, being chiefly involved either by abscess, pneumonia, or embolism; and the fact that the wear and tear of life falls more on the right lung than on the left, and that the former is about 10 per cent. larger in volume, accounts in some measure for this preponderance. Post-operative abscesses, especially those following tonsil and dental operations, occur more often in the upper lobes than do other pulmonary infections, which points to aspiration from the mouth and throat being less of an etiological factor than has generally been believed. The condition will generally respond to treatment by postural drainage and general hygienic measures, and operation is contra-indicated until it is clear that cure by other means is unlikely. In abscess other than post-operative, when the lung and pleura are not adherent, and the locality and the patient's condition are suitable, artificial pneumothorax may be useful. Preventive measures against the occurrence of post-operative abscess consist in precautions against inhalation of septic material by avoiding ether anaesthesia for tonsillectomy or dental operations when infection is present in the mouth and throat, but primarily in precautions against lowering the resistance of the lungs to infection.

### 32. Rupture of the Long Tendon of the Biceps.

N. BACKER GRÖNDALH (*Norsk. Mag. f. Lægevidenskaben*, March, 1923, p. 123) has, in the capacity of an insurance referee, recently seen three cases of rupture of the long tendon of the biceps of the arm. In none had the correct diagnosis been made, and the most common mistake would seem to be the diagnosis of rupture or hernia of the muscle itself. These mistakes are the more regrettable as they entail inappropriate treatment, such as massage, which is not only futile but may even do harm. The only satisfactory treatment is, in the author's opinion, operative reunion of the torn ends of the tendon at the earliest possible opportunity, before the muscle has retracted too much. Even when the damage is not repaired by operation this injury does not inflict great disability, and the Norwegian State Insurance Office awards only 15 to 20 per cent. compensation. The author illustrates his account of this accident with the record of a case of a workman who fell, receiving the weight of his body on his flexed arms. He heard three small snapping sounds in the right upper arm, which suddenly became painful. He felt unwell and vomited. The right arm seemed perfectly normal when it hung down; but when it was flexed at the elbow a soft, pseudo-fluctuating, spindle-shaped swelling appeared on the anterior exterior aspect of the upper arm. This swelling tapered away when traced upwards, and ended in a small firm knob. The long tendon of the muscle had apparently been torn at the junction of the tendon with the muscle, and no sign of the upper part of the tendon could be found.

### 33. Traumatic Rupture of the Intestine.

A. L. LOCKWOOD (*Canadian Med. Assoc. Journ.*, May, 1923, p. 311) points out that there are certain intra-abdominal conditions caused by external violence without penetration of the abdomen the diagnosis of which is always difficult and often impossible. The extent of the injury to the abdominal wall is no indication of the amount of damage to the viscera. Rupture of the intestine may be due to direct crushing, compression, tearing, or bursting of the intestine. The small bowel is involved much more frequently than the large, in the proportion of nine to one. The rent is usually transverse and multiple rents occur in one out of every five cases. The early symptoms include subnormal temperature and increase of the pulse rate; shock develops immediately after the rupture; respirations are thoracic in type. Vomiting is invariably present after an hour or two, and pain and tenderness are present in all cases. If the abdomen be distended and liver dullness lost operation is of little value and surgery

## B. THE ESSENTIAL NATURE OF THE SO-CALLED RHEUMATOID ARTHRITIS AND OSTEO-ARTHRITIS.

It is not my intention to describe in detail the pathological changes, since those occurring in osteo-arthritis have been described in detail by me elsewhere,<sup>1</sup> and the changes in rheumatoid arthritis have been described by many competent observers. We have already seen that the pathological processes have received interpretations of an extraordinary variety nature. Hence I propose to discuss shortly the true nature of the changes in the common types of chronic arthritis.

In the first pathological type, as Virchow pointed out, the disease commences in the central area of the articular cartilage and is associated with early "lipping" of the articular margin, although in rare cases this is absent. The synovial membrane is involved comparatively late, and never to the same degree as in the second type. This type of arthritis is known in this country by the name "osteo-arthritis." The well marked bony thickening with only slight changes in the synovial membrane and absence of "spindle-shaped" appearance of the joint, together with the usual moderate severity of the symptoms, form a well marked clinical picture. The earlier changes are very commonly seen *post mortem* in the joints of those who have passed the meridian of life.

In the second pathological type the process commences and remains more marked in the synovial membrane, and invades from the periphery. The formation of chondro-osteophytes, producing "lipping," is occasionally seen in the more chronic stages of the disease, but, as a rule, to a lesser degree and at a later stage than in osteo-arthritis. Pain and muscular spasm are more marked in this type and concurrent deformity is common in neglected cases. This type of arthritis is known in this country by the name "rheumatoid arthritis."

### TYPE I.—Chronic Arthritis in which the Disease Commences in the Articular Cartilage (Osteo-arthritis).

The first departure from the normal consists, to the naked eye, in an alteration in colour of the surface of the central area of articular cartilage, which loses its normal bluish-white translucent appearance, and becomes more opaque and of a yellowish hue. Microscopically there is an alteration in the staining reaction of the matrix; for instance, with eosin the superficial stains very faintly compared with the deeper layer of the cartilage. There is at this stage no alteration in the cartilage cells. At a slightly later stage the so-called "fibillation" of the matrix occurs at the surface of the central articular area. In a sense the term "fibillation" is a misnomer, as there is no formation of true connective tissue fibre, but a mere splitting of the matrix. This appearance of fibillation, as I have endeavoured to point out, is due to the peculiar structure of the matrix. If articular cartilage be steeped in brine for several days it will be seen that the matrix is arranged in alternating lamellae which lie horizontally in the superficial layers, form an irregular network in the intermediate zone, and constitute a palisade of vertical strata in the deeper layer. Histological examination shows that these alternate layers are formed by the more collagenous and the more mucinous elements of the matrix respectively. I believe that articular cartilage is nourished by lymph which percolates along these tracks, particularly the softer, more mucinous. I have little doubt also that the fibrillation is often due to the solution of the more mucinous tracks by toxic substances contained in the synovial fluid, whereby the more resistant collagenous elements remain as the so-called "fibres."

at this early stage. Occasionally the cells at the extreme surface undergo degenerative changes. The most striking sign, however, is that in most cases the cells exhibit no sign of diminished vitality, and very often groups of actively proliferating cells may be seen. It is very striking, even in advanced cases, to see the "fibres" containing groups of healthy proliferating cartilage cells. A still more important point is that the most active proliferation occurs at the margins of the clefts in the matrix. This variability and active proliferation of the cartilage cells appears to me to be the very antithesis of an atrophic or degenerative process, at any rate as far as the cells are concerned. To me it seems fairly evident that the cells proliferate in response to irritation. We thus see that as far as the central area of the articular cartilage is concerned, the change consists in a degenerative process in the cartilage matrix with proliferation of the cellular elements.

Shortly afterwards, or coincident with the above changes, the well known "lipping" of the articular margin occurs. This is caused by proliferation of the lateral part of the articular cartilage and of the underlying bone. As there is actual formation of new bone and cartilage cells, the term "hypertrophy" is a misnomer, but to regard the process as a pure degeneration is absurd. Later the cartilage on the surface of this new formation may undergo the same changes that we have seen to occur in the central area. As the cartilage disappears the subjacent bone becomes sclerosed from compensatory new bone formation. The deeper layer of articular cartilage is also invaded by vascular invasions of connective tissue which form new bone. The surface may thus be rendered bumpy—the epiphyseal echinodermatosis of Slavicek (Fig. 1). The sub-articular cancellous spaces are often of unusually open texture, due to a process of rarefying osteitis, and occasionally cyst-like spaces are in evidence. Some of these, I believe, may be due to cystic degeneration of islands of articular cartilage which have become isolated by the advancing tide of new bone formation.

Changes in the Synovial Membranes and Capsule. For a considerable period no obvious changes may be seen in the synovial membrane, but eventually the portions of the membrane nearest to the articular margin become more villous. There is a hyperplasia of all its elements with occasional areas of small-cell infiltration, but the later are rare compared with the second type, in which they are a prominent feature. Newly formed blood vessels are conspicuous, and show no evidence of arterio-sclerosis at this stage (Fig. 2). During this stage of increased vascularity there is sometimes a development of adipose tissue, cartilage, or bone in the synovial membrane, but never to the same extent as in the second type. This increased vascularity and cellular proliferation strongly negative the primarily degenerative or atrophic view of the disease. The fact that the synovial fluid is usually not deficient in nutritive qualities is shown not only by my analyses, but by the fact that synovial chondromatoma and peritriculair chondro-osteophytes may become detached and continue their growth with free in the joint. In the later stages the membrane and capsule may undergo sclerosis (Fig. 3) and with Hoffa and Wollenberg I have observed the occasional presence of areas of hyaline degeneration. Arterio-sclerotic changes may be seen in certain of the vessels of the synovial membrane, yet it is clear that these vascular changes advance *port passu* with the changes in the membrane. It is also clear that they are not of etiological importance, but are coincident, and like the changes in the membrane, inflammatory rather than degenerative.

Dr. Geoffrey Evans, in his recent investigations into the nature of arterio-sclerosis with special reference to its relation to chronic renal diseases, has brought forward evidence that the latter is usually inflammatory in nature, as is also the coexistent arterio-sclerosis—that the latter is not of etiological import, but that both conditions are probably due to the same cause. The author and Dr. Evans have arrived at similar conclusions concerning the etiological importance of arterio-sclerosis through different avenues of approach.

diagnostic curetting performed two months after the abortion showed microscopical evidence of a chorion-epithelioma, which after the subsequent hysterectomy proved to be of insignificant naked-eye dimensions. Large lutein cysts were present in both ovaries.

#### 40. Operative Treatment of Sterility.

R. v. STEINBUCHER (*Zentralbl. f. Gynäk.*, June 9th, 1923, p. 929) agrees with Graff that the operative treatment of sterility has altered little in the last thirty years. The operations performed are of three main classes: (1) Operations for widening the vagina; (2) operations for replacing a displaced uterus; (3) plastic operations on the tubes. It is the last-named type which the author discusses fully, having had many successes in the cases treated by him, even after prolonged sterility. The method advised by most authors to diagnose the permeability of the tubes is by means of passing air into the abdomen through the uterus and tubes by Rubin's apparatus. This, the author states, is not without danger, as the stream of air can easily be infected *en route* from an infected uterus or tubes and a pelvic peritonitis set up; there is less risk for the patient in doing an exploratory laparotomy, for if any obstruction is present it can be seen and treated at once. The author comments on the fact that sterility is often due to appendicitis, and it was in operating for that condition that he did salpingostomy in many of his cases; in his other cases the abdomen was opened for fixed retroversions, lutein cysts, pyosalpinx, etc., but never for acute salpingitis. The operation is done by slitting up the closed fimbriated extremity and placing the greater part of the surface of the ovary in the widened tube. The uterine end of the tube is stitched by bringing peritoneum to mucous membrane. The method of treatment ensures that every ovum discharged by the surface of the ovary passes into the tube, and the further success depends on the permeability of the uterine end of the tube for spermatozoa. This may be demonstrated by air inflation when the abdomen is open; if an obstruction is present the tube can be widened at that point. The inflation by air when the abdomen is open does not cause increased risk. The author concludes by stating that these plastic operations are usually carried out when laparotomy has to be done for some other cause—for example, appendicitis, etc.—but he does not agree with Graff that laparotomy should not be performed for sterility without first proving the impermeability of the tubes; he would advise an exploratory laparotomy for sterility in any woman who ardently desires offspring, the inflation being carried out if required when the abdomen was open.

## Pathology.

#### 41. Local Immunity to Staphylococcal Infection.

FOLLOWING on his researches on anthrax, in which he was able to demonstrate the peculiar sensitivity of the skin to infection with the bacillus, A. BESREDEA (*C. R. Soc. de Biologie*, May 19th, 1923, p. 1273) has conducted some experiments with a view to determining whether the same local susceptibility holds good for invasion with the staphylococcus. Having obtained a strain of this organism which was specially virulent for guinea-pigs and rabbits, he compared the effects of subcutaneous injection in vaccinated and unvaccinated animals. When 1 c.cm. of a twenty-four-hour broth culture was injected beneath the skin of a guinea-pig an extensive oedema appeared at the site of inoculation about twenty-four to forty-eight hours later. The overlying skin became hard and branny, took on a blackish colour, and finally sloughed off, leaving a large suppurating wound which was a long time in healing. To vaccinate the animals three methods were employed—the subcutaneous, the intracutaneous, and the cutaneous; this last being accomplished by using a compress soaked in the vaccine and firmly bound on to the previously shaven skin. The cultures employed were either filtered or killed by heat. It was found that though either of the two former methods of vaccination was successful in averting the skin lesion caused by injection of the living organism, undoubtedly the most efficacious mode was the cutaneous one. From this the author concludes that staphylococcal vaccination depends on a local immunity of the skin.

#### 42. Beri-beri and Epidemic Dropsy.

J. W. MEGAW (*Indian Medical Gazette*, May, 1923, p. 193) discusses the origin and prevention of the great variety of manifestations included under the term "beri-beri," many of which are possibly distinct conditions. The vast majority of cases occurs among persons who eat overmilled rice, and the disease practically never affects those who do not eat rice in some form. He does not consider that the vitamin B deficiency theory can explain every type of case, but admits

that some of the conditions met with may be of the nature of an avitaminosis, and that this theory cannot altogether be excluded. On the whole he inclines to the view that some form of food intoxication (possibly analogous to botulism) is the factor of greatest importance in the production of the different conditions encountered. The train of symptoms and the *post-mortem* appearances support this opinion. As the disease is known to be associated with the eating of old rice and to disappear when fresh rice is supplied, it is possible that it may be due to changes occurring during storage, whether in nutritional value or in the formation of an active poison. It occurs, too, among families subsisting without any obvious change of diet, which also supports the food intoxication theory, and leads the author to suggest the possibility of an accidental infection of rice by microbial agents. No cases have been known to occur among persons partaking of new and parboiled rice. There is extremely scanty evidence of any infectious element. Referring to measures of control and treatment, the author emphasizes the need for an appreciation of all the possible sources of origin, and puts forward the following necessary considerations: attention to hygiene, cutting off of the supply of rice on the occurrence of an outbreak, restriction to parboiled rice at ordinary times, and the provision of a diet which will fulfil body needs according to the standard of modern dietetics. Special attention, moreover, should be paid to the conditions of storage of all rice consumed. As the disease does not appear to be infectious, no antiepidemic measures are necessary. The author advocates further research on the conditions of occurrence and the reasons for the variations in the different types of the disease.

#### 43. Relation between the Virus of Vaccinia and New Growths.

C. LEVADITI and S. NICOLAU (*Ann. de l'Inst. Pasteur*, May, 1923, p. 443) find that if the pure vaccinal virus be inoculated into epithelial tumours of the rat or the mouse, it leads to an increase in the size of the neoplasm. Excised six or ten days later and rubbed on to the skin of a normal rabbit, this tumour provokes a confluent eruption of vaccinia. With sarcomata the result is different: the virus grows poorly or not at all, and is not infrequently destroyed altogether. From this it may be concluded that tumours of ecto-endo-dermic origin constitute an excellent culture medium for the virus, whereas those of mesodermic origin more or less completely prevent its growth. Similarly, if the virus be injected into the blood, it is found that epithelial growths absorb it and facilitate its culture, in distinction to sarcomatous growths which destroy it. The effect of the virus on cancerous tumours is to alter them in such a way as to render them incapable of being propagated by grafting. Sometimes this sterilization can be attained by a single injection of vaccine; at others three or four injections are required into successive grafts. It is found that in an animal which has been rendered immune to the virus by the usual process of vaccination the tumour is also refractory to the virus; but if the virus be injected into a tumour in an unvaccinated animal, no immunity is developed. The cancer cell is therefore different in its properties from the normal cell. It can be passively immunized, but is incapable of developing active immunity for itself.

#### 44. Bacterial Antagonism in the Genesis of Transmissible Lysis.

J. BORDET (*C. R. Soc. de Biologie*, May 12th, 1923, p. 1211) has endeavoured to confirm the work of Lisbonne and Carrère, who found that the *B. dysenteriae* Shiga, when grown in the presence of *B. coli*, develops a transmissible autolytic principle. Much the same technique was followed. Into a tube of broth just seeded with Shiga's bacillus a few drops either of a living culture of *B. coli* or of a culture of this organism killed by heat at 57.5° C. for half an hour were introduced and the culture incubated for four days. It was then killed by heat, and 30 drops transferred to a fresh tube of broth inoculated with Shiga's bacillus. After three or four passages it was found that an autolytic principle was elaborated, so that Shiga's bacillus did not develop for more than a few hours before clarification set in. A careful study of controls showed that the *B. coli* was responsible for the initiation of this autolysis. Further work made it evident, however, that the principle was originated, not by a process of bacterial antagonism, but owing to the fact that the strain of *B. coli* employed was itself lysogenic. By testing sterilized cultures of this organism on single colonies of the same strain, it was found that some of the latter underwent lysis, showing that the lysogenic property, though not evident under the ordinary conditions of laboratory culture, was yet possessed and perpetuated by certain particularly sensitive individuals of the strain.

*Suggested New Nomenclature.*

**Chronic Arthritis (A), Monarticular.**

(1) *Synovial Type* (O.T., Rheumatoid arthritis).—The disease commences and remains more marked in the articular membrane. Every gradation may be seen between the chronic types and the more acute forms which lead to ankylosis.

(2) *Chondro-osteous Type* (O.T., Osteo-arthritis).—The disease commences and remains more marked in the articular end, the synovial membrane being involved later.

(3) *Mixed Type*.—The disease commences simultaneously in the synovial membrane and articular end and the changes advance in *joint space*.

In all three types osteophytes may form at the articular margins, but in the synovial type they occur comparatively late in the disease, and in the more acute forms which lead to ankylosis are usually absent. The suggested nomenclature is obviously a primary classification. It is probable that further research will justify us in subdividing each type.

**THE NEED OF RESEARCH INTO ETIOLOGICAL ASPECTS.**

Clinical evidence often appears to point to an infective or toxic origin in many cases of chronic arthritis. In a certain proportion obvious infective foci are present, the treatment of which may produce amelioration or cure of the joint condition. In other cases a careful search fails to reveal any primary focus, but it should not be forgotten that this fact by no means negates the possible infective nature of the disease. For instance, chronic polyarticular arthritis may be ushered in by an attack of tonsillitis. The latter may entirely subside yet the arthritis remains, and the supposition is that micro-organisms have entered the circulation via the tonsil and have settled in the synovial membrane, where they proliferate and form their toxins.

A young man came under my care suffering from chronic gonorrhea with gleet. Gonococci were present in the prostatic smear. While under treatment he developed a spindle-shaped swelling of the interphalangeal joints of the hand exactly similar to rheumatoid arthritis. At this stage, however, examination of prostatic smears for organisms was persistently negative. The infective nature of his arthritis was therefore obvious on clinical grounds, although it could not be demonstrated bacteriologically.

Similarly in tuberculous diseases of a joint the primary focus is usually a matter of assumption rather than actual demonstration. It is clear that any possible primary focus should be treated not only for these special reasons but because thereby the general health of the patient is improved.

At the same time we must bear in mind that the treatment of the primary focus need not necessarily bring about the desired result if the organisms were already entrenched in the synovial membrane and joint structures, as on the clinical and bacteriological grounds sometimes appears to be the case. In these cases the treatment importance than concentrating on primary foci. How often the efforts of the medical man are devoted to the latter while the joints are allowed daily to become more stiff and deformed—an excellent example of a policy of "straining at a gnat and swallowing a camel."

For complete and scientific investigation, the important pioneer work of Blackland and Foynton and Paine requires for the bacteriological aspects of the problem are clamouring following up. From time to time bacteriological investigations of the synovial fluid have been made and have been usually negative. However, as an argument against the infective nature of these forms of chronic arthritis this fact is quite valueless; for we know that in the form of chronic arthritis occurring in such infective conditions as actinomycosis the fluid is usually sterile. What is required is examination of the synovial membrane and other joint tissues. The extent of the operative field in chronic arthritis has increased of late years, and if every surgeon would make a point of having all tissues removed from the joint systematically examined by a bacteriologist the evidence upon which my own investigations are now proceeding.

In conclusion, let me repeat that the stage is now set for my own investigations are now proceeding.

The source of infection was not discovered and no other cases of unexplained fever arose. The faeces of the other members of the family were examined, but no pathogenic

the bacteriologist and chemical pathologist in conjunction with the surgeon to march forward, inspired by the immortal advice of John Hunter to Jenner, who was "thinking" of investigating vaccination: "Do not think but try: be patient, be accurate."

It is my pleasant duty to thank all those who have assisted me in my researches. To Sir Arthur Keith I am indebted for permission to work at the Royal College of Surgeons of England and for much help. Professor Shattock has been ever ready with advice on pathological points. To my colleagues at the hospitals with which I am connected, and especially in the Medical and Surgical Units of University College Hospital, I owe a debt of thanks.

Hunterian Lecture, British Journal of Surgery, July, 1922: D.M.D., Fig. 5, 1st ed.

**A CASE OF FEVER DUE TO B. PARATYPHOSUS C.**

ERIC WORDLEY, M.C.P.D., M.B., B.Ch. Cantab.,  
PATHOLOGIST TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL,  
PLYMOUTH.

PARATYPHUS C fever appears to be rare in England, and only two previous cases have been described—one by Duggan and Urquhart (1920) and another by Andrews and Neave (1921). Possibly the disease is commoner than is imagined, but in many cases (as pointed out by Duggan and Urquhart) agglutinins are not formed in the blood, and often the diagnosis can be made only by isolation of the organism from the blood stream, or more rarely from the faeces.

A girl, aged 13 years, was under the care of Dr. Benson Young at this stage I saw the patient in consultation with Dr. Young. The spleen was not enlarged and no spots were noted. At this stage I saw the patient in consultation with Dr. Young. Blood count gave the following figures: Leucocytes 4,400 per c.mm., polymorphs 51 per cent., lymphocytes 47 per cent., hyaline 2 per cent. Agglutination to B. typhus and B. paratyphus A, B, and C was negative in a dilution of 1 in 50. The urine contained no pus and was sterile on cultivation. No pathogenic organisms were isolated from the faeces. From the blood a *B. paratyphus* B with the exception that ductile was not fermented, though this took about seven days. Acid and gas were also produced in dextrose, maltose, mannite, and glycerol. The organism was tested with some *paratyphus* C serum kindly sent me by Professor L. S. Duggan. It was agglutinated to the end point of 1 in 8,000, whereas with *paratyphus* B serum, with an end point of 1 in 400. On saturation of this stock *paratyphus* C serum with the bacilli isolated from the patient the following result was obtained.

The titre of stock *paratyphus* C serum before saturation with the bacilli was 1 in 100,000. The patient's serum was 1 in 100 = trace. Although the patient's serum did not agglutinate the stock *paratyphus* C antigen, her own bacilli were agglutinated slightly (1 in 100, trace) by her own serum.

The temperature slowly subsided and was normal in ten days from the onset of the disease. No complications ensued. The pulse throughout was high: it was over 120 during the first week of illness, and a fortnight elapsed before it was below 100. Frequent examinations were made of the faeces, using both the brilliant green emulsion method, direct plating, and the isolated method. Fourteen days after the first agglutination was performed the patient was again bled and her serum tested on *paratyphus* C antigen, with a negative result.

The source of infection was not discovered and no other cases of unexplained fever arose. The faeces of the other members of the family were examined, but no pathogenic

of the velvet growing directly on the bone without any intervening membrane (periosteum), the cells of the cutis resting on the osseous tissue contiguous the one with the other. The cutis is sessile on the bone. Analogies may be found in the human body under pathological conditions. It may be seen in exposed bone, in compound fractures of the tibia, with loss of soft tissues. The skin may then grow directly over the embryonic osseous tissue in the course of its formation, and, becoming rigidly attached, form an adherent cicatrix. The same may occur after amputations which have healed by granulation tissue, the skin becoming fixed to the osseous tissue, much to the detriment of the patient.

When an amputation has been performed in childhood through an arm or thigh, in the course of years, if the soft tissues are allowed to contract from disuse atrophy while the bone continues to grow, a conical stump may result. The bone gradually protruding through the soft tissues is covered only by a thin, stretched layer of cutis—chiefly stratum lucidum. Like the velvet in the antler the human skin tries to keep pace in covering the growing bone in its protrusion, but, unlike the velvet, it only succeeds in covering it by such a thin layer of closely adhering skin that it is liable to injury on slight occasion.

#### *The Methods of Growth of the Antler.—Analogous to Diaphyseal Bone.*

The frontal bone from which the antler springs is not the usual site of diaphyseal bone. The frontal is only covered by pericranium, to which even the "Orthodox School" does not assign osteogenic powers of a high order. The method, however, by which the stag's antler grows from the pedicle, though not identical, is somewhat analogous to the growth of a diaphyseal bone, emanating from a single epiphysis, there being no distal apposition or impediment to its growth. Notwithstanding the myriad of cells so rapidly produced within there is no jumbling or overcrowding, each one forms and takes its proper place according to hereditary behest.

Protoplasm is not a single homogeneous substance. It is complex, each particle holding fast through countless generations to its own particular type. The cell also is not merely the expression of a chemico-physical basis of life, but every particle of living protoplasm within it has a long hereditary history fixed in the structure of each of its various molecules. So that, in the swarming millions of cells within the antler, each one follows by hereditary law its ordered sequence.

#### *Metchnikoff's Belief as to Cause of Old Age and Death in Cells of Body Generally.*

Metchnikoff believed that in the body generally old age is not brought about simply from the arrest of the reproductive power of the cells, but that the cells of the body grow old on account of the impairment of the phagocytes and the invasion of the body by germs introduced through the large intestine. In this way senescence, decay, and death occurred.

#### *The Method of Death of the Cells of the Antler.*

In the deciduous stag's antler none of these factors obtain. The whole evolution, ultimate sclerosis, death, and separation of the antler is aseptate, and phagocytosis plays no part therein. The death of the bone is primarily due to increased osteoblastic formation encroaching centripetally on the lumen of the vessels, resulting in sclerosis of bone, and finally in ischaemic death. The osteoblasts extract from the blood the ossein, which they deposit in their periphery and build themselves in, cut off their food supply, and become entombed.

There is no senescence in the cells of the antler—they all die young. The mature period of osteoblastic formation is just reached and the completed bone cells formed when they, while still in the full vigour of youth, perish by their own reproduction. For them there has been no senility and no decay. They have built up a beautiful structure, and when they perish they leave behind a nerveless, bloodless, hard, dense bone as a weapon of offence and defence, which can bear without sensation the blows of adversaries.

#### *Why does the Osteoblast not Continue to Grow in the Antler Indefinitely?*

There is no physical obstacle to an upward expansion of the antler. The rejuvenation of the cells of the antler depending on the increase of nuclear material is abundantly evidenced in nuclear budding, and even in the possible formation of new cells produced by the shedding of nuclear buds, surrounded by a layer of cytoplasm—daughter cells—an extra method of cell production augmenting the ordinary cell division.

Though contrary to recognized methods of cell proliferation, the phenomena of nuclear budding and the possible production of daughter cells is suggestive of a supplemental mode of cell production. Such would aid in the rapidity of cell formation and in the rejuvenation of the cells exhausted by constant segmentation and requiring to make still further effort to multiply at a point so far removed from their base—the pedicle.

The nuclear budding and the formation of daughter cells—formed and thrown off—may mark the commencement of a new cycle in cellular proliferation (being physiologically comparable to the period of sexual maturity in multicellular organisms); in this way senescence in the cells is warded off and rejuvenescence is maintained.

#### *The Growth of the Osteoblasts outside of the Bone such as takes place after Fracture.*

In the outpouring of osteoblasts in the repair of bone bereft of its periosteum, such as in fracture, the same question arises in an intensified form, as the osteoblasts are then outside of their own direct nerve control. Why do the regenerating cells which have been actively proliferating know when to stop their reproduction? Why don't they go on producing indefinitely? Here heredity cannot play the same dominating rôle, as the factors are so variable and accidental circumstances are introduced which the osteoblasts must overcome. There must be conditions governing the product of the outpouring beyond the influence of the trophic nerves of the bone—which, however, may still have a "wireless" control of the osteoblasts, or which may have a limited, independent life within the living tissue.

It is observed that as long as the osteoblasts which have thus been poured out can be kept in their germinal state fixation by ossein and consolidation is warded off and reproduction of cells is continued. Constant movement of the parts is conducive to large outpourings of cells, which are prone to take on the cartilaginous formation and fixation is delayed. An abundant supply of thin-walled blood vessels greatly facilitates the deposition of ossein and so encourages fixation.

Reference may be made to the case of a seaman who got his thigh bone broken in its upper third aboard a vessel wrecked in the Bristol Channel. He was tied to a spar, and, being washed overboard, got stranded on a rock, his damaged leg swinging to and fro in the waves for forty-eight hours. He was afterwards rescued and lay in hospital for many months. As a result of the constant movement to which his leg had been subjected by the waves, a great tumour-like mass of bone formed in the thigh in the midst of the torn and lacerated muscles; for the relief of this he was ultimately sent to me. So great was the development of new bone that an extensive "quarrying" with chisel and mallet was required before the normal shaft was exposed and alignment could be effected. After operation rapid healing took place with only an inch of shortening.

#### *The Mature Osteoblast—A Typical Form of Cell.*

A definite form or type of cell is recognized in the mature osteoblast of the antler. This is contrary to the opinion held regarding the mammalian osteoblast in general, which is said to be only definable by function and not by any special histological character.

When this cell was first seen by me in sections, from the growing antler, it seemed so distinctive as to appear *sui generis* to the antler itself. Many sections from various parts of the antler were subsequently studied to investigate the origin of the osteoblast and to trace it through its evolutionary stage from the germinal layer until it assumed its mature form.

might produce osseous infarctions. It is fortunate that such a series of circumstances favourable to the transference of osteoblasts from one place to another by the blood stream seldom occurs.

The mature osteoblasts are of a size that does not render their transference by the blood stream easy, but if nuclear budding occurred and some of the minute buds covered with cytoplasm—daughter cells—were detached, their minute proportions would facilitate conveyance.

*Instance of Osteoblasts conveyed by the Blood Stream and deposited in the Cicatrix of a Laparotomy Wound.*

That bone sometimes forms heterotopically in the midst of the soft tissues and in the muscles is well known, and these instances are generally the result of accidental osteoblastic distribution following upon injury to bones and the tendinous expansion of the muscles inserted into them.\* Besides this, however, it is possible that osteoblasts in their germinal stage may be carried by the blood stream and may be localized by injury with extravasation of blood—in the same way as germs circulating in the blood stream may be located. An instance which bears this interpretation has just occurred, and has been communicated to me by my colleague Professor Muir, pathologist to the University of Glasgow, who has also given me some of the sections—which my colleague Mr. MacRae, whose case it was, gives me liberty to use.

The new bone was formed in a cicatrix in the midst of the abdominal muscles, at the site of a laparotomy wound made seventeen days previously. There had been no bone present in that tissue at the time of the operation.

It is probable that the original tumour in the intestine of the patient was one that secondarily involved bone, and that some of the osteoblasts had gained entrance into the blood stream and had been deposited at the site of the extravasation—the laparotomy wound. It is interesting that the typical mature form of osteoblast is seen in the bone sections situated in the cicatrix in the midst of the abdominal muscle.

*Miniature Antler: Bone grown in Glass Tube inside of Tissue.*

The bone grown in the glass tube experiments resembles in miniature the growth of the antler. The bone grown in the tube receives all its blood supply from its base in the pre-existing bone. The main artery of the bone in the glass tube passes up the centre, sending out branches which subdivide into capillaries, which are seen most abundantly at the periphery next the glass of the tube. It is round the thin-walled vessels that the osseous tissue first forms. Though generally these thin-walled capillaries intervene between the new bone in process of formation and the glass, yet in some places the osteoblasts are in actual contact with the glass, in the same way as the osteoblasts in the antler of the deer come into immediate contact with the dermal covering (the velvet) without the presence of any intervening membrane. There is here no periosteum—except the glass which acts the part of a limiting membrane. There is, therefore, no peripheral blood supply; it gets all its nutriment from the base, yet the bone thrives and grows rapidly and abundantly. The soft tissues surrounding the glass tube supply the proper temperature to facilitate the growth of its osseous contents, thus taking the place of the velvet in the antler of the deer.

*The Silver Ring Experiments and Deductions from them.*

Duhamel in 1739 placed a silver ring round a bone under the periosteum in a living animal and found some time after that the ring had become covered by bone. He inferred from this that the periosteum secreted bone, and his experiment and deduction therefrom have been accepted ever since, and have appeared in many of our textbooks during the last 184 years as one of the cogent reasons for our belief in the osteogenic functions of the periosteum.

The result of the experiment was correctly observed, but the deduction drawn therefrom was wrong and illogical. It was based on a single premiss. It has been demonstrated

by me that when the periosteum has been removed from the bone and silver rings are placed on the naked growing shaft, the new peripheral osteoblasts emanating from bone rapidly form over the nude surface and completely cover the silver rings, enclosing them in a mass of bone—greater than would have formed had the periosteum remained intact.

Whatever views one may hold regarding the osteogenic function of the periosteum, it is hoped that in practice no one would sacrifice an otherwise healthy bone merely because the periosteum, from traumatic or pathological causes, happened to be removed. As long as the nutrient vessels maintain the blood supply to the diaphyses, the shaft of the bone will live, grow, and function.

Even portions of detached living bone severed from all blood supply, preserved aseptically and replaced among the tissues in suitable conditions, have a probability of life. The osteoblasts of the detached bone receive sufficient pabulum from the blood serum until the fresh vessels of the part penetrate the bone and bring nutritive relief. New osteoblastic formation in the shape of a vigorous germinal layer ensues and quickly consolidates into new osseous tissue which aids in fixing the detached bone in its proper place and afterwards in performing the function of the shaft.

Recognition of these facts will prevent the removal of useful, although "bare," bone, and limbs may be saved that would otherwise be sacrificed.

*Bone Grafting: Report on Earliest Case.*

Nude bone has been grown heterotopically in various parts of the body—such as in the vicinity of the great vessels in the neck, in the muscles of the extremities, in the body cavity attached at the omentum, etc. Young, growing, nude bone may be transplanted, and it will live and grow in its new situation and will form part of the body of man, becoming homogeneous with him.<sup>3</sup> Forty years ago this was demonstrated,<sup>†</sup> and since then bone grafting and transplantation have been frequently employed, especially during and since the great war. Many surgeons at home and abroad have used it very successfully and extensively, none more so than Morison of Newcastle.

Reference may be made in passing to the earliest cases of bone grafting in order to report their present condition, as sufficient time has elapsed to demonstrate, more nearly than the recent cases, the ultimate results obtained.

The first was one in which a boy, aged 3 years, came under observation after he had suffered for several months from pyogenic osteomyelitis of the humeral shaft, the dead, blackened bone of the arm lying loose inside the remnant of the periosteal sheath lined with granulation tissue. The loose dead bone was lifted out. As belief in the periosteum as a bone producer was at that time still in vogue, it was hoped that some portions of the bone might form from the periosteum. This did not take place, and the wound healed, leaving an arm without a shaft. One year afterwards the mother returned with her boy, desiring that the arm be amputated, as she said it was not only useless but required the sound arm to look after it. The shaft of the bone had not grown. He had neither a fulcrum nor a lever, and when he attempted to flex the forearm on the arm the muscles and soft tissues of the arm contracting wriggled like a loose hanging rope, the forearm dangling helplessly at the end of it. Instead of acceding to the mother's request to amputate the arm, bone grafting was resorted to. The humeral shaft was restored by the introduction of young growing human bone, removed for the correction of deformity from the tibiae. Six pieces of bone—one each from six different legs of three different persons—were divided into small fragments and were inserted between the muscles of the arm where the shaft ought to have been. These fragments became firmly united to one another and to the epiphyses so as to form a solid shaft. It supplied the fulcrum and lever, and enabled the arm to function, the bone growing along with the growth of the body—but not quite proportionately to it. The greatest growth occurred subsequently, mainly from the proximal epiphysis which had been preserved in part,

1903. (Demy 8vo, pp. xiii+54; 32 figures, 2 plates. 1s. 6d. net.)

the blood pressure was below normal. The reaction to the Goetsch test was faint in all cases except one, in which it was moderate but less than normal.

So far, then, as the Goetsch reaction and the blood pressure are any indication, cases of dementia praecox, especially of the katatonic variety, appear to suffer from adrenal inadequacy.

Some years ago, in conjunction with Professor Halliburton, I undertook<sup>17</sup> a histological examination of the suprarenal gland of patients dying in Claybury Asylum, and we correlated the same with the chemical and physiological investigation of the adrenalino content of the gland. No definite results were obtainable, but this is not surprising, because the amount depends upon the cause of death and the time lapsing between death and the *post-mortem* examination. For this reason I did not think that comparative results by chemical and physiological investigations would be of value. I therefore resolved to pursue an investigation of the gland by the same histological methods as I adopted in the case of the reproductive organs. This work has been largely carried out under my direction by Dr. Emslie Hutton.

#### HISTOLOGICAL EXAMINATION OF THE ADRENAL GLANDS IN 100 CASES.

The material dealt with in this article was collected from patients who died in the London mental hospitals, and also hospitals for consumption and various military and general hospitals.\* In the majority of the mental cases the reproductive organs have already been examined, and work is going on at present on the thyroid and pituitary of these cases. So far as we have been able to ascertain from a search of the bibliography, there has been no complete systematic investigation of a similar nature.

One hundred cases were examined and classified, and the numbers in each group are tabulated below. The number in the class dementia praecox is large, the principal reason for carrying out the work being to afford an opportunity for determining if there is a change in the adrenal in this disease, the great importance of which is obvious from the fact that the bulk of incurable cases in mental hospitals belong to this group of the insanities. Moreover, many of the symptoms of this disease, as already indicated, point to an affection of the medulla of the adrenal gland. The number of hospital cases (which includes thirteen cases of death due to severe accident) is also large, for it is necessary to have a good picture of the normal. A comparatively large number of cases of tuberculosis in young adults were examined; these were required for comparison with cases of dementia praecox, the majority of whom die eventually from tuberculous affections. It has, indeed, been stated that 75 per cent. of the dementia praecox cases die of tuberculosis, and the hypothesis that tuberculosis stands in causal relation to dementia praecox might therefore be justified. Against this, however, is the fact that if this were so similar clinical symptoms and morbid histological changes to those found in dementia praecox should occur in cases dying of tuberculosis without mental symptoms. Moreover, some of the cases of dementia praecox died from pneumonia, dysentery, and suicide. These cases presented no signs of tuberculosis *post mortem*, although the histological changes in the reproductive organs and the brain were similar.

#### Classification of Cases.

|                                    |     |     |     |    |

100 cases.

#### Method of Examination.

It was impossible to arrange that the glands should be removed by the same person, but they were taken out care-

\* We wish to thank the superintendents and medical officers of the London County mental hospitals for kindly forwarding material and notes of the cases, also the pathologists to the general hospitals and hospitals for consumption who have assisted us by providing the material for this investigation. We are especially indebted to Dr. Roodhouse Gloyne of the City of London Hospital for Diseases of the Chest, Victoria Park, E.2, for material.

fully, and in most cases arrived in a satisfactory condition. They were thoroughly freed of extraneous tissue in the laboratory, each being weighed separately, and then hardened for two months in formol. Each was cut across in the same way, and as nearly as possible through the thickest parts of each gland. Sections were cut by the freezing method and were of approximately equal thickness; various stains were used, the chief of which were haematoxylin and eosin, Scharlach R. alone and with haematoxylin counter-stain. Most of the details of the fibrous and nuclear changes were observed in sections stained by the Del Rio Hortega\* method, or by that method counter-stained by eosin. The sections so stained were examined systematically. Their outline, magnified by means of an Edinger projection apparatus, was made; this showed very clearly the relative thickness of the cortex and medulla, and the general size of the organ. Means were also taken for obtaining an approximate idea of the relative amounts of cortex and medulla. The section was then microscopically examined and a full account of the appearances was recorded. The nuclear ratio in the medulla (to be explained later) was taken in each case.

Before proceeding to describe the morbid histological changes met with it is desirable to give a brief account of the weight and microscopic appearances presented by the normal human gland.

#### The Normal Adrenal Gland.

Each organ weighs from 6.5 to 7.5 grams, some, however, as will be shown later, weigh slightly more; the body weight must be taken into account when judging whether a case is lighter or heavier than the normal. According, however, to the very careful records of Kojima, body weight does not seem to have much influence.<sup>14</sup> The medulla is at least as wide as the cortex, and more often exceeds it in width at the thickest part of the gland. The cortex is composed of well defined polygonal cells, arranged in columns (zona fasciculata). Near the surface of the organ the columns have a more open arrangement (zona glomerulosa); near the medulla the arrangement is much more open (zona reticularis), and for convenience of description these terms will be used throughout this paper. The cells are well defined, and contain one, and sometimes two, darkly stained nuclei. They are packed with a glistening refractile lipid substance; this is, as a rule, present in all the cells of the cortex, but is sometimes absent from its innermost layers. In these latter layers are often seen brown pigmented granules tightly packed in the cell; their significance is not yet known.<sup>5</sup> The cortical adenomata, such as are described by Elliot<sup>7</sup> and Vasilescu,<sup>8</sup> have never been observed in this series of cases. The fibrous tissue of the cortex continuous with that of the capsule is well defined, but of delicate structure, and runs down in a septa-like fashion between the cells carrying the blood vessels and lymphatics. The medulla will now be described fully, as it is here that most of the more definite microscopic changes, especially in dementia praecox, have been observed. There is a light fibrous groundwork with fine offshoots surrounding groups of cells; there is no pericellular arrangement of the fibres. The cells have a different arrangement and differ in form from those of the cortex. They are arranged more loosely in irregular columns with large interspersed blood sinuses; a striking feature is the appearance of the large vessels with very thick muscular coats; generally speaking, the medullary cells are arranged around and in contact with these vessels. Sometimes, however, the sections show the cells of the zona reticularis arranged around and in close contact with them. The cells are polygonal and larger than those of the cortex;

\* **Nuclear Staining: Del Rio Hortega Method.**—Sections cut by the freezing method are taken from distilled water, placed into the silver solution (see below), and warmed at a temperature of 50° to 55° C. until slightly yellow in colour. They are then placed direct into a 2 per cent. solution of formol (neutralized by calcium carbonate) until the section becomes black; washed in distilled water for about one minute, and then placed into gold chloride solution (1 in 500) until the section becomes grey, usually about half a minute; then into a 3 per cent. solution of sodium hyposulphite for five minutes—in this it becomes a rose colour. Wash in water, fix section to slide, blot off excess of water, and dehydrate with a cresote-carbolic-xytol mixture (cresote 10 c.cm., carbolic acid 10 grams, xytol 60 c.cm.), and mount in Canada balsam.

**Silver Solution.**—5 c.cm. of a 10 per cent. solution of AgNO<sub>3</sub>, precipitated by 20 c.cm. of a 5 per cent. solution of sodium carbonate; dissolve precipitate by a few drops of ammonia, and add water to 55 c.cm.

THE SUN CURE FOR SURGICAL TUBERCULOSIS.

By invitation of Sir William Treloar and his co-  
fessities, a visit of inspection to the Cripples' Hospital and  
College at Alton, Hants, was recently paid by the vic-  
presidents, companions, and local honorary secretaries of  
the Queen Alexandra League, which was founded to collect  
money for this institution. The visitors assembled first in  
the recreation room, where Sir William Treloar presided  
and encouragement from Queen Alexandra. He explained  
which between them raised more than £9,000 last year for  
the hospital at Alton. He then asked the Right Hon. Sir  
Clifford Albutt, M.P., Regius Professor of  
Physics in the University of Cambridge, to address the  
meeting.

Having indicated his pleasure at being able at length to see the work carried out at Alton, Sir Clifford answered that at first sight it seemed almost a misapprehension to invite one who was not a surgeon to speak of the achievements of Alton; but Sir Anthony Bonby, to whom he mentioned this objection, answered: "No! you are right to go because the glory of Alton is that it has defied surgery; it does surgery without surgery." Sir William Treloar had had his reward complete than he could have dreamed of, bringing them out peace and consolation only, but bodily repair also, and in most cases restoration to health. Calling science to his aid, he associated with himself Sir Henry Gairdner, who thereupon achieved success, not merely by his dexterity and resource as a surgeon, but by pressing into his service other new and beneficent agencies, such as climate, sunlight, and artificial radiations. A striking example of the accurate adaptation of means was seen in the operation of sunlight as a powerful remedy, administered at Alton and Hayling by precise dose and distribution.

of tuberculosis from the time of Hippocrates, who well described the pulmonary form. It was not until Koch's discovery of the bacillus in 1882 that medicine held the clue—the *Mycobacterium tuberculosis*—by which to trace and identify the pest in all its insidious penetrations in the bodies of man and many domestic animals.

The old conception of disease (Sir Clifford continued) as a thing to be cast out, had given place to phases of reaction. The morbid process and its cure were intrinsic natural reactions which fortunately could be governed with some begins a footnote."

And here Sir Henry Gauntin has proclaimed "Back to Hip- which shall deal with the accessible and the inaccessible. given up as beyond hope of treatment, a system must be devised the reach of the knife; so that, if these parts are not to be infected parts, such as the vertebrae for instance, are out of a little less than that of the active disease. Furthermore, some in the joints especially, a deformity may be perpetuated only as Nature's own powers might well repeat, yea, of anything is now merely yet describing the general system, of reacting in

[illegible]

The following are drawings of sections through that part of the adrenal gland where the medulla is thickest. They are drawn from the slide preparation by aid of an Edinger apparatus with a magnification of 2.5.

FIG. A.—Section of adrenal gland of a male, aged 20, who died from suppurative encephalitis two months after a severe bullet wound of the head. Note the extensive medullary portion.

FIG. B.—Section of adrenal gland of a case of general paralysis of the insane of two years' duration. Note the extensive medullary portion.

FIG. C.—Section of adrenal gland of a case of epilepsy who was for three years before death in a mental hospital, where she died of tuberculosis, aged 38 years. Note the extensive medullary portion.

FIG. D.—Section of adrenal gland of a case of dementia praecox who was for five years in a mental hospital, where he died of dysentery, aged 30 years. Note the extensive area of the medulla, which stains black because it is composed almost entirely of thick strands of fibrous tissue.

FIG. E.—Section of adrenal gland of a case of dementia praecox who was for two years in a mental hospital, where he died of pneumonia at the age of 25 years. Note the narrow strip of medulla, which is deeply stained because of the fibrous tissue which largely composes it.

FIG. F.—Section of adrenal gland of a case of dementia praecox who was for sixteen years in a mental hospital, where she died, aged 33 years. Note the narrow strip of medullary tissue, which, however, is not deeply stained, as there is no marked fibrosis present.

FIG. G.—Section of the adrenal gland of a case of dementia praecox who was for two years in a mental hospital, where she died, aged 29 years. Note the narrow strip of medullary tissue.

the naked eye that there was abundance of lipid present throughout the cortex; the cortical cells in the three zones were filled with coarse to fine droplets of this refractile substance. In a few of the dementia praecox cases dying of tuberculosis lipid was entirely absent, and in many it was reduced in amount to a variable degree. In one case who died of dysentery it was entirely absent. It was absent also in two cases of head wound where death was caused by septicaemia. It was also absent or much reduced in amount in cases of young adults dying from tuberculosis.

It may be said that the lipid was absent or diminished where acute or chronic septic conditions were present. This is in agreement with what other workers, among whom are Elliot<sup>7</sup> and Mott, have found, and supports the view that it is an important source of antitoxins. It cannot be said that the lipid content seems to have any kind of relationship to the mental condition of the patient. It has, probably, as Mott<sup>8</sup> has shown, an important relation to the function of reproduction. In one of the cases of dementia praecox of this series, the testis was absent on one side and on that side the adrenal gland was one-half the size of the other. A full account of this case was given in a previous communication.<sup>18</sup>

(b) *Fibrous Septa*.—Several of the cases showed thickening of the septa, but this did not seem to have any relation to the different classes of case. A fair number of general paralytics, and also a proportion of the normal cases, showed this appearance. When this was present in the cortex there was not always a corresponding fibrosis in the medulla.

(c) *Cells*.—It was not observed that these showed any definite changes. In the zona reticularis in some cases of dementia praecox active mitosis was seen, but it was not generally present; here, too, chromaffin granules were observed in some of the cases.

(d) *Lymphocytic Infiltration*.—In many of the general paralytic cases it was observed that along the lines of the fibrous septa there was an infiltration of small lymphocytes. In some cases there were definite clumps of these small lymphocytes near the outer part of the cortex, but more often the appearance was simply one of infiltration along the fibrous septa. In one of the hospital cases this appearance was present, but in no other case was it observed.

#### Changes in the Medulla.

It was in the medulla that the striking changes were seen; the first of these—namely, the differences in the amount of medulla present in the gland—has already been dealt with, and the microscopic changes will now be discussed.

(a) *Cells*.—In dementia praecox, even in very early cases, there were distinct cellular changes. Sometimes these changes were only found in some of the cells and many normal cells were present. The cells were as a rule smaller than the normal, and their cytoplasm was much vacuolated. The cell nuclei varied much in shape and size, and were generally smaller than the normal nucleus, though they were larger in proportion to the cell; they were not always round and many tended to be oval. They also stained poorly and showed fewer and finer granules than the normal nucleus, and many exhibited a very faint and simple chromatin network. Syncytia containing numerous polymorphic nuclei were frequently seen. There were a great number of nuclei present which were not surrounded by cytoplasm; these either occurred in patches or were diffused throughout the medulla. These nuclei were nearly round, but tended to be oval or fusiform, and many were larger, paler, and contained fewer chromatin granules than the nuclei seen in cells. In various psychoses, such as manic-depressive cases, somewhat similar changes were found, but never to such a marked

varieties of advanced disease, each of which had to be dealt with in a different fashion. He further advocated hospitals for tuberculous single persons in place of common lodging-houses, and in this connection did not hesitate to recommend the establishment of a civil caravan.

Dr. A. FRANKS LEWIS (Assistant Physician, Royal Infirmary, Edinburgh) and Dr. EDWARD WATT (Medical Officer, Scottish Board of Health) continued the discussion, which was wound up by Dr. JOHN ROBERTSON.

#### *Surgical Tuberculosis from Milk.*

The afternoon session had for consideration "The extent and nature of the damage done by tuberculosis derived from infected milk." The discussion was opened by Mr. J. D. WATSON in an interesting paper in which he described his first experimental efforts under the auspices of the Birmingham Drainage Board to obtain a tuberculo-free dairy herd. The scheme adopted was a modified form of Bang's isolation method. This possessed the merit of simplicity and was capable of being put into operation without elaborate preparations. The two main objects were to rear healthy calves from stock certified to be free from tuberculosis and to segregate the healthy from the unhealthy cows. Experience soon proved that the ideal aimed at could not be attained immediately without pecuniary loss. All the reactors, therefore, were not disposed of at once, the younger cows being kept and bred from, a pedigree bull certified to be tuberculo-free having been first obtained. Recurring tests appeared to point to the satisfactory conclusion that, by the maintenance of a consistent procedure, it was possible within four years of its initiation, and at small expense, to eliminate tuberculosis from a herd of short-horn cows, which on the first test showed 60 per cent. to be suffering from the disease.

Sir GEORGE BARTHOLOMEW said he strongly supported the view that tuberculosis was not transmitted by inheritance. A certain delicacy or vulnerability of tissues, however, was transmitted. It appeared to him that within recent years there had been a decided diminution in the number of cases of tuberculosis of the bones and joints. Dealing with the points raised by the last speaker, he did not consider the complete extirpation of tuberculosis from dairy herds a practical proposition at the present time. In these circumstances he was of opinion that a Commission should be set up by the Ministry of Health to settle once and for all, if possible, the value of pasteurized milk. There were still conflicting views on this question. Tuberculo-free milk could be got, but he warned the public to see that they got what they paid for in such a case.

Dr. JOHN FRANKS (Surgeon to the Royal Hospital for Sick Children, Edinburgh) also contributed a paper to the discussion. He could not agree that the incidence of surgical tuberculosis showed any sign of diminution up to the present, war conditions and more recently the widespread unemployment with its attendant poverty probably being contributory causes. The great majority of cases of tuberculosis were infected during early childhood when resistance to infection is low, and the manifestations of later life were the recrudescence of this early infection. No limit could be set to the period during which the living bacillus might exist in the human body even without any clinical manifestations of tuberculosis. He believed that bony infection, which was but another name for milk infection, was responsible for the vast majority of cases of surgical tuberculosis. The first essential of pure milk was a herd of tuberculin-tested and preferably home-bred healthy cows. The most rigid attention to hygiene in the necessary handling of the milk should also be enforced.

Sir HENRY GAVATY, by the aid of some beautiful lantern slides, brought vividly before the Conference the terrible ravages of surgical tuberculosis in childhood. In his opinion the wonderful result of treatment of such cases at Alton and Hayling Island. This treatment was costly, however, and many thousands of children had to undergo terrible suffering unnecessarily as the result of a polluted milk supply. The present position cried urgently for redress. There should be more open-air and sun schools to increase brass workers could be divided into two main groups: Hospital showed that the ailments particularly affecting of 3,000 out-patients attending the Birmingham General tion of zinc. An analysis of the occupations and ailments exposed to extremes of temperature as well as to the inhale wet doors, and that in the casting shops the men were at times and that they very frequently had to stand on the "dipping" shops were exposed to the inhalation of the brass trade processes. medullary cells showed atrophy and vacuolation of the cytoplasm, but the nuclei showed but little deviation from the normal and there was little or no fibrosis. The medullary nuclear ratio was the same as in normal cases. In many of the cases the lipid was entirely absent, and in nearly all of the remainder it was diminished in amount.

It will thus be seen that the histological appearances were different from those in dementia praecox. It might have been suggested that the changes in the adrenals of the dementia praecox cases were due to the tuberculosis from which they so often die. But this is not a fact, for twelve cases of tuberculosis occurring in young sane adults were examined with the above negative results. It may be observed that no lymphocytosis was observed in these twelve cases. There were, however, three cases, which were not used, as they showed tuberculous foci in the medulla. None of the many cases of dementia praecox that died of tuberculosis showed tuberculous foci in the adrenal glands. Another argument against the change in the medullary cells being due to tuberculosis is that some of the cases of dementia praecox died of dysentery and pneumonia after a short illness, and these presented no signs of tuberculosis at the *post-mortem* examination.

#### Extracts from Cases.

Space does not permit of extracts from all the cases, so eleven have been selected, and very brief notes appended. Two are hospital cases, four are cases of dementia praecox, two are cases of psychoses, one is a case of general paralysis, and two are cases of tuberculosis.

#### CASE I.

Case of duodenal ulcer; death occurring after operation. Adrenals weigh 10 grams and 9.5 grams respectively. The cortex and medulla are in normal proportion to each other; abundant lipid is present in the cortex in all its layers, and there is no evidence of fibrosis. The medullary cells are of the normal shape and size, they stain well and show little or no vacuolation. The nuclei are round and of a uniform size and shape; they stain deeply and show many chromatin granules, some coarse and darkly stained, and others of dust-like fineness. The nuclear ratio is 1.2 per cell.

#### CASE II.

McK., aged 19 years. Admitted to Charing Cross Hospital ten days after accident. The wound was in the mid-dorsal region, and was foul and septic; there was complete paraplegia, and death occurred seven days later of septicaemia. Adrenals weigh 9.7 and 12.5 grams respectively. The medulla is large and wide and in normal proportion to the cortex; lipid is entirely absent throughout. There is no fibrosis, and the medullary cells show a typically normal appearance. Nuclear ratio is 1.1.

#### CASE III.

W. F. S.; dementia praecox. Male, aged 18 years at death. He was for two years in a mental hospital, where he died, and before admission was said to have been ill for only four months. He was fairly intelligent, but childish mentally and physically for his age. He was hallucinated for general sensation and had curious feelings in his legs, upon which he based various delusions. He was quiet and depressed and was distinctly anergic, and on admission was certified as adolescent melancholia. For six months after admission he improved slightly, but then began to deteriorate and became apathetic, untidy, and anergic. He rapidly became more demented

and developed tuberculosis, from which he died. Adrenals were small and weighed 3.9 and 4.3 grams respectively. The medulla showed marked pericellular fibrosis, and there was scarcely a normal cell present. The nuclear ratio is high.

#### CASE IV.

P.; dementia praecox. Female, aged 29 years at death. She was for two years in a mental hospital, where she died. Before admission there was several months' history of strange behaviour, moodiness, solitariness, and abstraction; she had one child. On admission she was restless, excited, impulsive, and disoriented. She was emotional, wept for no apparent reason, then laughed in a senseless fashion, grimaced and rolled her eyes. Six months after admission she showed negativism, and stereotypy of manner and speech. Six months before death her health began to be very poor and she became anaemic, cyanosed, and the extremities were oedematous. The Goetsch reaction was faint. She was stuporose and the breathing was shallow and slow. Tuberculosis was suspected, though physical signs were negative, and there was no rise of temperature. Gradual emaciation occurred and death. *Post-mortem* examination showed extensive pulmonary and intestinal tuberculosis. Adrenals: The medulla of this organ is a mere strip of tissue, and in this few normal cells can be seen. The cells are small and atrophied, there is considerable fibrosis, and the marked nuclear changes already described are found. The nuclear ratio is high.

#### CASE V.

G. T.; dementia praecox. Male, aged 37 years at death. He was for four years in a mental hospital, where he died from pulmonary tuberculosis. He was a typical case of dementia praecox of the type where progressive dementia is the most marked symptom. The adrenals weighed only 2.3 and 3.9 grams respectively and are small and shrunken in appearance. The medulla shows a pericellular fibrosis, and many of the cells are atrophied. There are, however, a fair number of almost normal cells. There are advanced nuclear changes and the nuclear ratio is high.

#### CASE VI.

R. M. W.; dementia praecox. Male, aged 19 years at death. He was for eight months in a mental hospital, where he died of exhaustion; there was nothing else to note in the *post-mortem* examination. He was a typical case of dementia praecox. There was a bad family history: his mother and father were aged 20 and 21 years respectively at their marriage, and have been separated for eighteen years. The mother was violent and drank heavily; the maternal grandmother died in a mental hospital; a maternal uncle and an elder sister were in a mental hospital at the same time as the patient. On admission he was sullen and depressed, but subject to attacks of acute excitement, when he was most impulsive and resistant. He steadily deteriorated mentally and physically. Adrenals: The organs are of normal size, and the medulla is not diminished in extent. The medullary cells vary to a considerable extent, some being normal and others being atrophied and showing much vacuolation of the cytoplasm. There are nuclear changes, but these are not very advanced and the nuclear ratio is low.

#### CASE VII.

E. B.; mental defective with polyglandular insufficiency. Female, aged 18 years. She died four days after admission to hospital, and at the *post-mortem* examination military tuberculosis was found. Little was known of her history as she was brought in by the police as a lost child at the age of 4 years and was at a special school. The adrenals weighed 2.5 and 4 grams respectively. The medulla shows fibrous hyperplasia and the cells vary greatly; some are normal and others show atrophy and vacuolation. The nuclei vary greatly in size, and there is a high nuclear ratio.

#### CASE VIII.

C. B., male, aged 50 years; melancholia. He was in a mental hospital for three years, where he died of pulmonary tuberculosis.

### DESCRIPTION OF SPECIAL PLATE.

FIG. 1.—Drawing of a section of medullary portion of the adrenal gland of a male, aged 20 years, who died as a result of a bullet wound of the head; stained Del Rio Hortega method. (A macroscopic drawing of this gland is Fig. A.) Note the light fibrous groundwork, the abundant cytoplasm of the cells, the nuclei, which vary little in size or staining, and which contain abundant chromatin granules, both coarse and fine. (Magnification 80.)

FIG. 2.—Drawing of a section of medullary portion of the adrenal gland; stained Del Rio Hortega method. A case of dementia praecox who was for two years in a mental hospital, where he died of pneumonia at the age of 25 years. (A macroscopic drawing of this gland is Fig. E.) Note the fibrous groundwork, which tends to be pericellular and show scanty cytoplasm, and some of the cells show a collapsed body. The nuclei are irregular in size and in intensity of staining; they contain fewer and on the whole finer chromatin granules than the nuclei in Fig. 1. (Magnification 80.)

FIG. 3.—Photomicrograph of a section of the medullary portion of the adrenal of the same case as Fig. 1, but the magnification is much less; stained Del Rio Hortega method. (Magnification 450.)

FIG. 4.—Photomicrograph of a section of adrenal gland of a case of chronic pulmonary tuberculosis in a man who died at the age of 32 years. Stained Del Rio Hortega method. The fibrous groundwork is light; the cells show exhaustion of the cytoplasm, which is small in amount and shows vacuolation. The nuclei, however, are of equal size, and show abundant chromatin granules, both coarse and fine. (Magnification 450.)

FIG. 5.—Photomicrograph of the medullary portion of the adrenal gland of a case of general paralysis of the insane, to show the infiltration with small lymphocytes that occurs here and there throughout the gland. A few cells are seen at the corner of the photograph, and these contain abundant cytoplasm and nuclei, which are regular in form and staining, and which contain abundant chromatin granules. (Magnification 350.)

FIG. 6.—Photomicrograph of a section of the medullary portion of the adrenal gland of a case of dementia praecox who was for eighteen months in a mental hospital, where he died of pneumonia following influenza at the age of 21 years. The cells in this case vary much. In parts, as at the top of the photograph, can be seen cells which approach the normal in appearance. Throughout the specimen small cells are seen, the cytoplasm shows vacuolation, and the nuclei show variation in size. (Magnification 450.)

FIG. 7.—Photomicrograph of a section of the medullary portion of the adrenal gland of a case of dementia praecox who was for sixteen years in a mental hospital, where she died, aged 33 years. (Fig. F is a macroscopic drawing of the whole gland.) Note that the fibrous background is slightly thickened, that the cells are small, and that the nuclei are surrounded in some cases by a very small amount of cytoplasm, and in some cases none is present. The nuclei vary in size and in staining. (Magnification 450.)

FIG. 8.—Photomicrograph of a section of the medullary portion of the adrenal gland of a case of dementia praecox who was for two years in a mental hospital, where she died, aged 23 years, of tuberculosis. (A macroscopic drawing of this gland is Fig. G.) Note the coarse fibrosis and the cells, which are atrophied. Some of the nuclei have no surrounding cytoplasm. The nuclei show variation in size. (Magnification 450.)

FIG. 1.—Microscopic section of an epi-articular echondrosis ( $\frac{1}{16}$  in. obj.). The deeper layer of the cartilage is being invaded by inroads of vascular connective tissue from the subjacent bone. In these inroads are many multinucleated "chondroclasts."

FIG. 3.—Fibrotic synovial fringes in later stages of osteo-arthritis. No marked alteration in vascularity.

FIG. 4.—Tuberculous "osteo-arthritis." Parts removed by excision from the knee-joint of a young adult. The synovial membrane is markedly villous, and in places contains caseous nodules. Microscopic examination shows that these contain tubercular material, in addition to the caseous matter, and that the

FIG. 2.—Synovial fringes from osteo-arthritic joint. Note vascularity with fatty infiltration in certain places. There is a complete absence of arterio-sclerosis.

FIG. 5.—Experiment II: Experimental production of osteo-arthritis. Osteoculture of streptococcus obtained from joints of case of osteo-arthritis injected into knee-joint of rabbit. Appearance after six weeks; a, commencing osteophytic growths; b, villosity of synovial membrane.

FIG. 6.—Drawing showing the typical appearances in chronic non-tuberculous arthritis of the synovial type (so-called rheumatoid arthritis). A A. Remains of the degenerate articular cartilage, in which many of the cell groups have undergone necrosis and the matrix is fibrillated in places. B B. Pannus of connective tissue derived from the synovial membrane which is spreading over the surface of the cartilage (A), which it is invading and replacing. C C. Irruption of newly formed osseous tissue which has invaded the articular cartilage from below and joined forces with the aforementioned surface pannus. D D. Well marked areas of inflammatory small-cell infiltration, some of which occupies a cancellous space. See microscopic appearance of synovial membrane from this case (Fig. 7). From the knee-joint of a man, aged 45, upon whom synovectomy was performed through the author's patello-displacing approach.

FIG. 7.—Microscopic appearance of the synovial membrane from the knee-joint of a man, aged 45, upon whom synovectomy was performed through the author's patello-displacing approach.

socialist, who proclaimed one more failure of voluntary effort, one more evidence for the need of State control. Then came a counter-reaction, and people began to inquire personally, locally, and by commission whether things were really so bad as was alleged. It appeared that the position was certainly not hopeless, and that the voluntary system had certain advantages over State administration, as displayed in Germany, which made it worth while to attempt to continue it.

To the development of this opinion the investigations of Sir Napier Burnett and his reports to the Joint Council of the Order of St. John and the British Red Cross Society have largely contributed. His latest report—that for 1922—just issued<sup>1</sup> will encourage the friends of the voluntary system to increase their efforts to perpetuate what is one of the finest examples of the capacity of the British race to organize and administer its own institutions.

Sir Napier Burnett's report is concerned with the voluntary hospitals in Great Britain, but excludes London, because the hospitals in that area are under the supervision of King Edward's Hospital Fund. The hospitals in England and Wales and in Scotland respectively are treated separately, but the results are combined in an interesting introduction. The report is founded on returns from 643 voluntary hospitals (87 per cent. of the whole) containing 49,331 available beds, or 94 per cent. of the total. The number of new patients treated was 2,090,853, at a total cost to the hospitals of £4,946,299. The total number of new in-patients treated at the 643 hospitals was 501,945, and the total number of new out-patients 1,588,910. The number of 643 hospitals is made up of 571 in England and Wales and 72 in Scotland. The total number of new in-patients in England and Wales was 403,036, and in Scotland 98,909. The new out-patients in England and Wales numbered 1,277,338, and in Scotland 311,572. An interesting piece of information is given in a table from which it appears that thirteen teaching hospitals in England and Wales were responsible for 30 per cent. of the total patients treated by the 571 hospitals—approximately one-third of the whole. In Scotland six teaching hospitals were responsible for 51 per cent. of the total patients treated at the 72 hospitals, or more than one-half of the whole.

In a note which Sir Arthur Stanley, chairman of the Joint Council, has prefixed to the report, he calls particular attention to the facts stated by Sir Napier Burnett with regard to cottage hospitals, under which heading are included hospitals with less than thirty beds; in England and Wales there were 314 in 1922—an increase of 13 as compared with 1920—and in Scotland 41, an increase of 2. The total number of beds provided in these hospitals in England and Wales rose from 4,271 in 1920 to 4,572 in 1922; in Scotland the increase was from 552 to 607. The total number of beds in cottage hospitals in Great Britain was 5,179, but of those approximately 2,000 remained idle throughout 1922. Sir Arthur Stanley's comment is also to the governors of hospitals in crowded districts, who are always faced with a long list of patients awaiting admission.

In a section of his introduction dealing with the investigation of the cause and nature of disease, Sir Napier Burnett divides the work done in hospitals into two categories: "defensive," when the patient is admitted to hospital for the purpose of treatment, and "offensive," when the patient is admitted to hospital for the purpose of preventing the spread of disease.

admitted to hospital for the repair of damage already done, and "offensive" work, which seeks to a certain admission to the hospital. "It is," he says, "even yet too little recognized by the public that the great and ever-expanding science of preventive medicine owes its existence in large measure to the work carried out in the hospital laboratories." In the case of the larger hospitals he states that laboratory accommodation has been evolved during the past twenty-five years from a single room and one trained worker until there is now a pathological and bacteriological institute attached to many of the hospitals complete in all departments and staffed by highly trained workers, each a specialist in his own particular subject. With regard to smaller hospitals, he says, "the gratifying information is to be found in many annual reports that during the past few steps have been taken to establish some form of laboratory accommodation." "But," he adds, "the establishment of adequate laboratory patient consideration, owing to the cost involved and the question of the supply of the requisite trained personnel." This last is undoubtedly a most important point, and some how or other means must be found for making hospital laboratory work a career to which a man may devote his life. Such work is on the borderline of research, and with proper encouragement the border may in many cases with great advantage be overstepped.

In discussing the financial situation attention is directed to the fact, not always sufficiently appreciated, that the voluntary hospital system as a whole is to an important extent dependent upon the endowments provided by earlier generations. In the case of 666 hospitals with regard to which particulars have been obtained in this respect, the total amount of invested funds is over seven millions sterling, yielding an annual income of nearly £800,000. There was a great improvement in the financial position of the voluntary hospitals in Great Britain in 1922. In the previous year (1921) their ordinary income failed to meet the ordinary expenditure by £419,138; in 1922 the corresponding figure was £74,978. A remarkable fact brought out by the analysis of the returns is that 378 (57 per cent.) of the 666 hospitals had an excess of ordinary income over ordinary expenditure of £315,420, whereas the remaining 288 hospitals had an excess of expenditure over income of £390,398. In 1921 the percentage of over income of £390,398. In 1921 the percentage of over income of £390,398. In 1921 the percentage of over income of £390,398.

THE BRITISH EMPIRE CANCER CAMPAIGN.

We mentioned last week that a discussion had taken place between representatives of the British Empire Cancer Campaign and of the Royal Society and the Medical Research Council with regard to the organization of the scientific side of the campaign, and that it had been decided to form an advisory committee if the necessary agreement upon details could be reached. We had assumed that negotiations would proceed between the two parties in order to reach a full agreement on all details, but we learn from a statement in the Times that at a meeting of

# THE NATURE OF THE SO-CALLED RHEUMATOID ARTHRITIS AND OSTEO-ARTHRITIS.

## SUMMARY OF

AN INVESTIGATION INTO THE PATHOLOGICAL CHANGES, WITH  
A PLEA FOR A SCIENTIFIC CLASSIFICATION.\*

(With Special Plate.)

BY

A. G. TIMBRELL FISHER, M.C., F.R.C.S.ENG.,

ASSISTANT IN THE SURGICAL UNIT, UNIVERSITY COLLEGE HOSPITAL;  
SURGEON WITH CHARGE OF OUT-PATIENTS, SEAMEN'S (DREADNOUGHT)  
HOSPITAL, GREENWICH.

The chronic forms of arthritis known in this country by the somewhat unscientific names "rheumatoid arthritis" and "osteo-arthritis" are among the commonest of all human ailments, and probably cause a greater loss of productive energy to the community than disease of any other system. It is true that the disease rarely, if ever, causes the death of the patient, but it often occurs in the comparatively young and active, to whom the resulting cripplehood is a grave hardship. It is proposed in this paper to resist the temptation to discuss clinical aspects and treatment, and to review briefly certain aspects of the problem.

## A. UNDERLYING REASONS FOR THE PRESENT STATE OF THE ARTHRITIC PROBLEM.

### 1. Ignorance of the Physiology of the Articulations.

It is a striking fact that until quite recently our ignorance of some of the most elementary facts concerning the articular cartilage and the functions of the synovial membranes and fluid was almost mediaeval. Claude Bernard wrote more than half a century ago with regard to the synovial fluid: "les données physiologiques sur ce liquide sont a peu près nulles: le siège anatomique de sa sécrétion est lui-même très peu connu." It is somewhat of a reproach that these words are well-nigh as true to-day as when written. Even otherwise exhaustive treatises on physiology either ignore the subject altogether or dismiss it in a few lines as one of minor importance. My own halting and imperfect efforts in this realm will be briefly touched upon below.

### 2. Ignorance of Normal Intimate Histological Structure.

There exists great variance of opinion concerning the histological structure of articular cartilage and synovial membrane. With regard to the former, some hold that a perichondrium is present over the whole surface, others that it is present at the periphery only; while another school, following Ogston, hold that the superficial cells are in reality degenerate, and are in process of being cast off into the joint. With regard to the synovial membrane, hardly any two authorities agree as to the nature of the cells with which it is lined. In regard to its connexions, Schafer states "they are not connected with the lymphatic system;" but by injecting colloidal silver solution into the knee-joint of a living animal I was able to show that absorption by the lymphatics definitely occurs.

When faced with such multiplicity of views it would appear sufficiently obvious that the course to adopt is not to argue but to look and see. This is the method I adopted, and what I saw has been described by me in a recent Hunterian Lecture upon osteo-arthritis. Some of the main points will be briefly enumerated below.

### 3. Ignorance of the True Nature of the Pathological Changes.

It is clear that before we can hope to treat any disease on rational lines we must have a clear conception of its essential nature.

At the outset we are faced with contradictory views. For instance, Goldthwait christened the two groups, which we in this country usually call rheumatoid arthritis and osteo-arthritis, as atrophic and hypertrophic arthritis re-

spectively. Nichols and Richardson, however, classify them into proliferative and degenerative arthritis. Thus the condition that we know as osteo-arthritis is interpreted by the former as a process of hypertrophy and by the latter as a degenerative process. Some may say, "This is very interesting, but how does it help the unfortunate sufferer?" I would reply that it is of fundamental importance in prognosis and treatment. If we accept the view that the disease is some form of degeneration having an obscure relation to old age, it is difficult to see how treatment can be of any avail or how the disease can be arrested. If, however, we accept the view that the disease is inflammatory in nature, it is clear that the disease assumes an entirely different complexion, and that we should not leave a stone unturned until we have discovered the source of the toxic substances that bring about these inflammatory changes. Moreover, like other inflammatory processes, they may come to a natural termination. Instead of a depressing policy of *laissez-faire*, we adopt a more active and cheerful outlook. I have known individuals who have been labelled "senile" arthritis of the hip converted from lives of painful cripplehood to an active and comparatively painless existence. I propose to give a short description below of my conception of the nature of the changes.

### 4. A Confusing Nomenclature.

One of the commonest mistakes in this connexion lies in the investigator endeavouring to form a primary classification according to his conception of the nature of the pathological changes. Owing to the diversity of the latter confusion is bound to ensue. Another common error lies in mixing anatomical, clinical, and pathological subdivisions in the same classification. A good example of this lies in the terms "osteo-arthritis" and "rheumatoid arthritis." The former name is given owing to the supposed site of the principal changes, and is therefore anatomical. The latter term is a pseudo-clinical term in which the disease is compared, in terms reminiscent of the humoral pathology, to yet another disease, the etiology of which is still unsettled.

### 5. Lack of Co-operation between Physician, Surgeon, and Pathologist.

Specialism has its advantages, but we should never lose sight of its drawbacks and dangers. The policy followed at present is to divide many diseases into more or less arbitrary stages—the domain of the physician and surgeon respectively. Such divisions are obviously illogical and unnatural, and are among the most serious impediments to progress with which we are faced. We see the same lack of co-operation between physician and surgeon in the treatment of such conditions as gastric and duodenal ulcer. If we are to have specialists, let us have those who will make a thorough study of a system or organ and be responsible for the treatment of its disorders from beginning to end, whether operative or non-operative.

The surgeon's share consists very largely in dealing by operation with the failures of medical treatment. The last twenty years have seen a great development of elaborate surgical technique; but I believe and trust that before the present century terminates we shall see a more healthy co-operation between physician and surgeon in the direction of the prevention of those advanced states that at present demand operation.

Sir Robert Jones has with great courage frequently protested against the existing lack of co-operation, and, thanks largely to his efforts, there has undoubtedly been improvement. It is unfortunately still only too common to meet with gross deformities which should never have been allowed to occur; and, on the other hand, for individuals to endure unnecessary pain and suffering because the physician has not acquainted himself with the possibilities of surgical measures in overcoming deformity or in restoring movement to the stiff joint. At the special Ministry of Pensions clinic at Orpington such co-operation exists, and the results, which have been most gratifying, lead one to believe that an extension of such clinics in civil life would be of great advantage.

\* The expenses of this research were defrayed by the Medical Research Council, to whom my thanks are due.

advertising. Sir Sydney Russell-Wells, M.P., who also responded, described the House of Commons as one of the best houses of detention in this country; its keepers were called whips, and if its inmates were allowed out at all they were only allowed in pairs. Sir Eric Geddes, whose important speech came almost at the end of the banquet, spoke on the lack of frankness in the discussion of insanity, the exceptional nature of the treatment, and the financial difficulties in providing the dual treatment, physical and mental, and the special environment necessary to the cure of the mental case. He said that although the Medical-Psychological Association was over 50 years old it would not claim for itself that it had explored more than the fringe of the subject of the cause, prevention, and cure of insanity. During the last ten years the recovery rate appeared to show practically no improvement. Therefore, maintained a great field of research, alike among cases already in institutions and those not sufficiently advanced to require certification. If the case were put before the public clearly and definitely he was sure that the authorities, national and local, in this country would undertake their purse-string. The public must be made to realize that a large proportion of the inmates of these institutions, constituting an inextinguishable drag on the utilitarian part of the population, could be cured, but that the possibilities of investigating each case on scientific lines were limited by lack of funds for education and research, so that those concerned could do little more than trust to Nature and environment to remedy what they knew might be remedied with more speed and certainty by scientific means. Apart from what might be called the physical side of the treatment in disease of septic or toxic origin, and the removal of nerve strain and shock, there was also a field which to himself as a layman appeared almost unexplored—that, namely, which awaited the psychiatrist.

#### MEDICAL SERIALS IN BRITISH LIBRARIES.

Last week reference was made (p. 75) to the list of periodicals in medicine and the allied sciences prepared by Professor R. T. Leiper, F.R.S., Professor of Helminthology in the University of London, with the collaboration of Mrs. H. M. Williams and Miss G. Z. L. Le Bas, M.Sc., and it was stated that the British Medical Association, impressed by the need for such a guide to the principal medical libraries in Great Britain, had subsidised the preparation of the work and was about to publish it in a volume. We have now received an early copy of the volume, which makes a very handsome appearance. The periodicals noted are classified geographically: English-speaking countries and their possessions (p. 1-72), French-speaking countries and their possessions (p. 73-102), Teutonic countries (p. 103-143), Slavonic countries (p. 144-159), Scandinavian countries (p. 160-166), Latin countries, including Italy, Portugal, Spain, Mexico, and South and Central America (p. 167-186), and other countries, including Greece, Turkey, Japan and China (p. 187-190). The main object has been to save the time of persons desiring to consult the very scattered literature, especially of the sciences allied to medicine. Professor Leiper has dedicated it "to those who have made the weary pilgrimage of London's Libraries," but, as has been said, the list embraces also the Libraries of Oxford, Cambridge, Liverpool, Manchester, Edinburgh, and Glasgow. The aim has been to make an approximately complete list of periodicals, including serials of learned societies available in Britain. Over 4,700 periodical publications are included, and it is hoped that few important titles prior to 1921 have been omitted. The list indicates not only the name of the periodical and of the libraries in which it is to be found, but also the range in each library.

#### OPENING DOORS.

This is the title of a little book written by Dr. John Thomson "for the mothers of babies who are long in learning to behave like other children of their age." The author first describes the way in which the mind of the "normal infant develops, so that the mother may know when the baby's brain is growing properly"; then he shows how she may know "when the baby's brain is not growing as fast as usual"; and lastly he instructs her as to what she can do to bring about an improvement. Many excellent books have been written giving advice to mothers; Dr. Thomson does not merely give good medical advice, but he gives it with insight and kindness. Written in very simple language, this unpretentious book is pervaded by that indefinable charm which we find in a work of art and scarcely hope to discover in a book of medical advice. Dr. Thomson shows an appreciation of the fact that where a mental defective is found in the home the physician has not merely to treat a case, but has to deal also with a painful and delicate domestic situation. The feelings of the parents have to be considered, especially in the early days when they dimly begin to recognize that the baby's mind is not developing properly. Dr. Thomson has not thought of this reason not only insight into the mother's feelings; for this reason not only will the mother of a defective and this book help her "to open the doors of her child's mind," but she will find quantities of *Opening Doors*. By John Thomson, M.D., Edinburgh: Oliver and Boyd, 1933. (Pp. 20. Price, in cloth 1s. 6d.; in paper, 6d.; and in paper (dust cover) 2s. 6d.)

At the quarterly meeting of the Council of the Royal College of Surgeons of England on July 12th, Sir John Bland-Sutton was elected President in succession to Sir Anthony Bowlby, who had held office for three years. At the same meeting Sir Berkeley Moynihan, Bt., professor of clinical surgery in the University of Leeds, and Mr. H. J. Waring, surgeon to St. Bartholomew's Hospital and Vice-Chancellor of the University of London, who became the Middlessex Hospital from 1866 to 1920, when he was appointed consulting surgeon. He was President of the Royal Society of Medicine in 1921, and last January gave the Hunterian oration before the Royal College of Surgeons, of which he was then vice-president. He gave the address in Surgery before the British Medical Association at the Annual Meeting at Aberdeen in 1914; in the course of this address, which dealt with the surgeon of the future, he said: "It requires little foresight to recognize that for men ambitious to attain high places in surgery the high road lies through the pathological institute." Of this truth he is himself a living example, and one evidence of his faith is afforded by the Bland-Sutton Institute of Pathology at the Middlessex Hospital. It was built and equipped by him in 1914, and through it, as the departments of the medical schools are brought into it.

*Traumatic Osteo-arthritis.*

This type deserves a few separate words. It is a purely localized form, in which the central part of the articular cartilage undergoes the changes that we have already enumerated owing to its being exposed to an undue degree of mechanical trauma or stress acting over a long period. Sir Arbuthnot Lane has rendered a great service by pointing out that this type is not a disease, but rather the series of compensatory changes that occurs in a joint in response to altered stress. This type, as Lane pointed out, is often occupational.

The nature of the pathological changes in osteo-arthritis supports the view that these changes are the response of the joint structures to irritation, either mechanical or toxic, and are inflammatory in nature; that these changes are both degenerative and proliferative, both processes often advancing *pari passu*; that the different reaction to the cause may largely be accounted for by the fact that the lateral articular area is better nourished than the central.

The theory of general diminished nutrition of the joint structures is negated by the proliferation—often marked—that occurs, and by analysis of the synovial fluid; moreover, arterio-sclerosis is probably not of etiological importance. Proliferative changes also negative the theory that the process is one of atrophy due to old age. Hence such a term as “*morbus coxae senilis*” is a misnomer. I venture to give the following definition: Osteo-arthritis does not constitute a disease *sui generis*, but rather the series of physiological or pathological changes that ensue in a joint when it is subjected to prolonged or oft-repeated injury, either mechanical or toxic, but of a moderate degree of intensity. The causes are therefore very varied, and there can be little doubt that the future will bring to light additional factors in its causation of which we are at present ignorant. Osteo-arthritic changes, for example, occur with greater frequency in certain disorders of the ductless glands, such as acromegaly, than can be ascribed to mere coincidence. Whether in these cases the joint changes are due to the action of toxins formed from failure of the ductless gland to supply the necessary link in the chain of metabolic endogenous products, or whether in some way the resistance of the joint to bacterial toxins is lowered, it is impossible at present to state.

The relation of osteo-arthritis to the group of auto-intoxications due to defects in the excretory apparatus or to the accumulation in the body of products of normal metabolism is still undecided, but two groups emerge concerning the etiology of which we have a little more evidence. The following preliminary classification is therefore adopted: Group 1, traumatic osteo-arthritis; Group 2, osteo-arthritis due to bacterial toxins. Examples of Group 2 are well seen after many infective forms of arthritis. It is not generally recognized that the condition may occur in certain chronic types of tuberculous disease (Fig. 4). I have also succeeded in producing an infective type of osteo-arthritis experimentally<sup>2</sup> (Fig. 5).

TYPE 2.—*Chronic Arthritis in which the Disease Commences in the Synovial Membrane (Rheumatoid Arthritis).*

Clinically every stage of acuteness may be seen, from the subacute polyarticular or monarticular, in which pain or spasm are so marked that deforming contractures are liable to develop, to the more common type, also polyarticular or monarticular, in which spasm or pain are less marked features, and therefore limitation of movement is less likely to accrue. Different types are also seen, which have been so carefully described by Nichols and Richardson in America and by Strangeways in this country that I do not propose to discuss them in detail.

Some little confusion has, however, been produced by the introduction of the term “*atrophic*.” For it is now almost generally recognized, save by those who “*have eyes and see not*,” that the process is primarily of a pronounced inflammatory nature, and that when atrophy occurs this may be largely accounted for by disuse. As in osteo-arthritis, however, degenerative changes may accompany the proliferative. These may be seen, for example, in the

articular cartilage, and the latter is often for this reason invaded and replaced by a pannus of granulation tissue derived from the synovial membrane and by ingrowths of vascular connective tissue from the subjacent cancellous spaces (Fig. 6). In the more chronic forms there may be no pannus, but mere fibrillation of the cartilage. This absence may be due to the movements of the patient which are possible owing to the less severe nature of the pain, and which militate against the progress of this tide of granulation tissue. In the synovial membrane inflammatory collections of small round cells in the vicinity of the vessels are prominent features (Fig. 7). As in the first type of arthritis, adipose tissue, cartilage, or bone may be developed in the synovial fringes. Periarticular lipping certainly occurs, although somewhat later than in the first type of arthritis. I believe it to be Nature's way of endeavouring to extend the articular surface, and is therefore more commonly seen in the more chronic cases where movement has been continued and sclerosis and contracture have not occurred.

C. SOME PHYSIOLOGICAL FACTORS UNDERLYING THE PATHOLOGICAL PHENOMENA.

I believe that the extraordinary difference between the behaviour of the central and lateral articular areas in these chronic forms of arthritis can be explained by a principle that I have endeavoured to establish—namely, that the lateral part of the articular cartilage is better nourished than the central, and is, moreover, furnished with a perichondrium in which lie blood vessels derived from the *circulus articularis vasculosus*. The central poorly nourished area responds to the cause of osteo-arthritis by degeneration, whereas the lateral part proliferates. It is possible that pressure may play a rôle—although I believe a minor one—in causing the different reaction. I found, on examination of a considerable number of cases of osteo-arthritis of the knee-joint, that in nearly every case the changes commence in the central articular areas of the patella and trochlear surface of the femur, and *not* where pressure is greatest upon the femoral and tibial condyles. The phenomena of repair of articular cartilage confirm the view of its nutrition. I was able to produce experimentally a traumatic form of osteo-arthritis by the simple expedient of removing the central part of the articular cartilage, when compensatory proliferation of the better nourished lateral area occurred, producing characteristic “*lipping*.”

It is instructive to study the appearances seen in cases in which a simple transverse fracture of the patella has occurred some years previously and in which the fragments have maintained good apposition. It will usually be seen that firm bony union is present; that there is usually no repair of the breach in the central part of the articular cartilage, but that the breach in the lateral portions on either side has been repaired. The adjacent articular cartilage is almost invariably fibrillated. It is probable that the condition we designate “*traumatic osteo-arthritis*” is in reality a physiological rather than a pathological process.

D. SUGGESTED SCIENTIFIC NOMENCLATURE.

We have already criticized some of the existing nomenclatures and offered the opinion that any attempt to classify the forms of chronic arthritis according to the supposed nature of the pathological changes is, owing to the complexity of the latter, undesirable.

Clinical or pseudo-clinical classification leads to great confusion. A satisfactory classification must fulfil the following requirements: it must be simple, scientific, and accurate, and non-reminiscent of mediæval empiricism. Let us hope that an era will soon dawn when “*rheumatism*,” “*rheumatoid*,” and allied terms will be banished from scientific language. I suggest that the term “*chronic arthritis*” is simple, scientific, and accurate, since it indicates its inflammatory nature. How, then, are we to differentiate the various types? I suggest that the differentiation should be according to the site of origin, which is also the anatomical site of the principal changes. I may perhaps attempt to tabulate as follows:

presented on several occasions in Europe and in America. Professor Wilhelm (Lélie), as President of the International Committee, expressed the thanks of the gathering to the members of His Majesty's Government, and to the members of the British Committee, particularly the Honorary Secretaries, Sir Percy Power and Mr. Roberts, who had taken charge of the organization of the Congress and had arranged for the visitors a cordial and brilliant reception. It was the first time that the International Congress of Surgeons had met under the leadership of a surgeon belonging to the country in which the meeting took place. The previous five congresses had been held, three in Brussels, one in New York, and one in Paris, and on each occasion the president had been a foreign surgeon. It was that day that

organisms were isolated. As a precaution the other inmates of the house were inoculated with a *paratyphosus* C vaccine, and, as stated above, no fresh cases of infection arose.

## THE RELATIVE CONCENTRATION RATIOS OF SOME CONSTITUENTS OF THE URINE.

(Abstract.)\*

BY

S. W. F. UNDERHILL, M.A., B.M., B.Ch.Oxon.,

ASSISTANT LECTURER AND SENIOR DEMONSTRATOR OF PHYSIOLOGY,  
ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.

THE "filtration-reabsorption" theory of renal secretion states that the glomeruli filter off from the plasma its dialyzable constituents, some of which are reabsorbed, together with water, by the tubules, thus leading to a concentration of the remainder: the former are described as "threshold," and the latter as "no-threshold" bodies respectively.<sup>1</sup> If two "no-threshold" substances are present together in the plasma, are filtered off by the glomeruli, and are concentrated in the tubules by the absorption of water, the degrees to which they are concentrated should be the same in each case. The "concentration ratio" is the ratio of the amount present in the urine to that in the plasma (expressed in percentages).<sup>2</sup> The experiments to be described were performed to determine the relative concentration ratios of some of the so-called "no-threshold" constituents of the urine; urea, inorganic phosphate, and creatinine were chosen for this purpose. They are present in a "free" (that is, dialyzable) condition in the plasma, and appear to be equally distributed between plasma and corpuscles *in vivo*, so that estimations made on the plasma give the amounts available for filtration through the glomeruli at that moment. As, however, it has been stated that urea and inorganic phosphate are present solely in the plasma *in vivo*, entering the corpuscles after the blood is shed, unless precautions are taken to avoid injury to them,<sup>3</sup> some preliminary experiments were performed on the distribution of these three substances between plasma and corpuscles in the blood of the cat, since this animal was used for the later experiments. It was found that urea and creatinine were evenly distributed under normal conditions: after injection intravenously, the same even distribution might be found, or there might be more in the plasma, while there was always more inorganic phosphate in the plasma than in the corpuscles after it had been injected into the blood stream.

The experiments on the concentration ratios were performed on decerebrate cats: a solution of the substances about to be examined was injected intravenously, a blood sample taken shortly afterwards, and a further sample after a variable length of time, during which the urine was collected; in some experiments further samples of blood and urine were obtained. The blood samples were oxalated and centrifuged, and the plasma used for the analyses. For calculating the concentration ratio the plasma percentage was taken as the mean of the analyses of the two samples obtained at the beginning and end of the period during which the urine was collected.

It was found that the creatinine was always concentrated to a greater extent than the urea—from two to five times more in the different experiments. This occurs whether the plasma or urinary concentrations vary or remain constant during the course of an experiment. The fact that the results obtained when the plasma concentrations are constant are comparable with those obtained when these concentrations vary, suggests that taking the mean plasma concentration for calculating the concentration ratio introduces no appreciable error.

Comparing the concentration ratios of inorganic phosphate and urea, it was found that the phosphate might be concentrated to about the same extent as the urea, or up

to about three times more; but it was always found to be concentrated to a less degree than the creatinine in the same experiment. The degree of concentration seemed to depend directly on the amount of phosphate injected, being greater when the kidney had to remove a larger amount from the blood stream. If the concentration ratio of urea is taken as unity, those of creatinine and inorganic phosphate relative to this as standard can be plotted on a chart, and it is seen that there is a general parallelism between the ratios of the latter two, which possibly depends on the rate of blood flow through the kidney.

The fact that urea, inorganic phosphate, and creatinine may be concentrated to different degrees by the kidneys during excretion is difficult of explanation on the filtration reabsorption hypothesis. If the modification be accepted that the urea is partly reabsorbed in the tubules,<sup>4</sup> these experiments show that the hypothesis must be still further modified to admit of partial reabsorption of the inorganic phosphate also. It seems more probable that the tubule cells secrete these substances independently, according to the requirements of the moment. On the other hand, the facts are consistent with the view that selective reabsorption takes place in the tubules, the fluid absorbed varying in composition at different times. A fairly definite relationship was found between the excretion rates of the three substances in experiments in which several samples of urine were obtained: the factor correlating the excretion rates is presumably the blood flow through the kidney.

The experiments give data for calculating the rate of disappearance of the injected substances from the blood stream, taking the initial blood volume to be 5 per cent. of the body weight. Within two minutes of the completion of the injection, 75 to 90 per cent. of the injected urea and creatinine is no longer to be found in the blood; the loss is most rapid at first, and then the rate slackens until a balance is struck between the concentrations in the blood and in the tissues; the concentration in the blood may now remain fairly constant in spite of excretion in the urine, since the tissues act as a reservoir of the substances in question. The injected inorganic phosphate leaves the blood more slowly, and only about 65 to 80 per cent. disappears into the tissues.

## THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

OBSOLETE DIAGNOSTIC CRITERIA.

BY

W. McCONNEL WANKLYN, B.A.CANTAB., M.R.C.S.,  
L.R.C.P., D.P.H.

ANYONE who wishes to gain a really sound grounding in this subject will be well advised to assign beforehand their true value to certain traditional criteria with which he may have been equipped as a student. There are certain phenomena which frequently occur indeed, but are not pathognomonic in the hour of trial for the purpose of distinguishing between small-pox and chicken-pox. Into this category fall umbilication, shottiness, palatal and buccal lesions, lesions on the sole of the foot, cropping, uniloculation. Not one of these is a real friend in need; and the first four may prove to be very unreliable in the matter of the assistance which they offer.

In my article in the Jenner Memorial Number of the *BRITISH MEDICAL JOURNAL*, dated July 5th, 1902, on "The differential diagnosis between variola and varicella," the following observations were made: "It is well at once to say that the words 'shotty' and 'umbilicated' are mere broken reeds to lean upon in the matter of diagnosis. The expressions are pernicious in two ways: Their absence in a case suspected to be small-pox is taken as evidence against that disorder, and their presence in a case otherwise suggestive of varicella is held to negative that disease. The words are fetishes, or objects of superstitious worship, which help their devotees as little as do most idols, and

\* The full paper is published in the *British Journal of Experimental Pathology*, 1923, vol. 4, pp. 87 and 117.

developed lymphatics. It might have as one of its functions the removal of oxygen from the blood, so preparing it for the action of the liver upon it. While the function of the normal spleen was unimportant, the diseased spleen was a serious menace to the contents of the blood and to the liver. The action of the spleen might perhaps be pathological processes in which it was concerned, but acted as a secondary agent. Removal of the organ in the splenectomy and in certain blood diseases removed a pathological agent or broke up a vicious circle. In the estimation of the benefit to be derived from its removal the entire syndrome of which it was a part must be considered. A chronically enlarged spleen which did not yield to reasonable treatment should be removed early unless in the individual case there were contraindications to splenectomy.

Summary of 304 Splenectomies.

The number of splenectomies performed in the Mayo Clinic for various conditions up to June 1st, 1923, was 304. All deaths occurring in the hospital are classified as due to the operation, without regard to the length of time following operation, or to the cause of death.

*Splenectomy due to liver-organism.*—(1) Syphilis, chronic, 8 splenectomies; 1 death in hospital, good results in 7; (2) tuberculosis, 4 splenectomies; 1 death in hospital, good results in 3; (3) pyogenic organisms, 15 splenectomies, 4 deaths in hospital, good results in 6; no patient with acute endocarditis was cured; (4) splenic anæmia, 4 splenectomies; 11 deaths in hospital, good results in the great majority of the remainder. A number of the patients who made good recoveries had typical Banti's disease with advanced portal cirrhosis. Ten patients had gastric hæmorrhages during the first six years following operation, and died directly or indirectly from that cause.

*Hæmolytic icterus.*—Forty-four splenectomies; 1 death in hospital; 40 patients recovered perfectly; 60 per cent. of the patients had coincident gall stones which required operation.

*Polycythæmia Rubra Vera.*—One splenectomy, great improvement; the patient is able to work more than former years.

*Hæmorrhagic Purpura (Essential Thrombopenia).*—One splenectomy, in advanced stage of disease; good recovery.

*Splenomyeloidosis (Leukæmia).*—Twenty-nine splenectomies; 1 death in hospital, great temporary benefit in 22. Six are alive and able to work, one more than 6 years following operation. The condition of the blood is improved, but not normal. There is less anæmia and less evidence of toxæmia in splenectomized patients.

The 61. mellancholic cases, many of which had not been accurately classified, were not discussed in this paper.

Dr. Ch. Wilkx of Liège, (who spoke), and Dr. N. Goodman, of Ghent, next presented their report on the surgery of the suprarenal capsules. The two parts of the suprarenal gland were morphologically, functionally, and embryologically distinct. There were two main groups of suprarenal tumours—those of cortical and those of medullary origin. The speaker would call the first cortico-suprarenal tumours, those of cortical and those of medullary origin. This was better than the term "hyper-nephroma," which had been first reserved for the tumours of Graafitz and had now spread to include all tumours of cortical origin and even of some formed from medullary tissue. Amongst cortico-suprarenal tumours there were:

- (1) Simple hyperplasias, which Virchow called "stroma-lipomatous suprarenals," usually very small, well defined, and sometimes formed of clear vacuolated cells, charged with lipoids—clear-celled adenomata, another type was composed of darker cells, sometimes pigmented, situated deeply in the cortex—dark-celled adenomata. These adenomata often underwent cystic degeneration.
- (2) Cortico-suprarenal carcinomata. Their clinical course betrayed their perihelionoma. Character rather than their histological structure.
- (3) Carcinomata of cortical tumours tending towards sarcomatous transformation. Against the cortical group might be placed the tumours of medullary origin. These tumours were of two separate origins and types, for two kinds of tissue existed within the suprarenal medulla.

(4) Carcinomata of cortical tumours tending towards sarcomatous transformation. Against the cortical group might be placed the tumours of medullary origin. These tumours were of two separate origins and types, for two kinds of tissue existed within the suprarenal medulla.

neurotic origin; (5) of paraganglionic origin. Of tumours of paraganglionic origin there were several types: the neuroblastoma or neurocytoma; the ganglio-neuroma; tumours of the ganglio-neuroma type were much rarer than paragangliomata. Histologically these had the appearance of chromaffin tissue; they were essentially innocent and often underwent cystic degeneration. Repton had called them innocent adenomata paragangliomata. Only one case of malignant paraganglioma had been described. The cortico-suprarenal tumours were by far the most frequent of all these tumours. They were found at any age. The whole group profoundly affected the secondary sexual characteristics. In embryological life they led often to pseudo-hæmaphroditism. In babies they led to precocious development of the external genital organs, and in girls to a tendency towards masculinity. In the adult woman the tumours accompanied a progressive masculinization; a beard or moustache might appear, there was shrinking of the breasts, the contour of the thighs became masculine. In men there was testicular atrophy and swelling of the breasts. More frequently these cortico-suprarenal tumours showed less definite symptoms, they remained latent and could not be paraded. In infants orbital metastases showed an oedema or papilled ecchymoses, often thought at first to be due to trauma. In the adult the metastases showed a remarkable predilection for bone. Little interest would attach to a metastatic metastasis if the metastases showed a remarkable predilection for bone. Little interest would attach to a metastatic metastasis if the metastases showed a remarkable predilection for bone. Little interest would attach to a metastatic metastasis if the metastases showed a remarkable predilection for bone.

Whatever might be the opinion of the physiologists as to the significance of adrenalin in the physiology of the suprarenal glands, the clinician continued to admit the suprarenal insufficiency resulting from a total deficiency in the suprarenal function, and not a deficiency of adrenalin alone. Moreover, the syndrome of Sergeant-Barnard presented an acute form, corresponding to the destruction of the glands, and a lighter form which corresponded probably to partial lesions and was still a matter for controversy. The acute form had the appearance of an intoxication, while the chronic form presented a principal symptom the hyperæmia and the asthenia. This syndrome showed the alteration of the gland without any gross information as to the nature of this alteration. The entire amount of suprarenal substance, had been performed, especially for epiradic disease, according to the opinion of some physiologists who think that these conclusions do not depend upon the nervous central system, but upon the endocrine glands. The results obtained were interesting, but the problem was far from being solved. The removal of the suprarenal gland had also been performed in cases of hypertension, so as to reduce the suprarenal functions. Of the two ways which had been used for the extirpation of the healthy suprarenal, the trans-peritoneal way, according to the technique of the speaker, was more advisable, being more accurate and giving the required view.

Mr. Percy Sanger discussed pituitary surgery. He would, he said, try to point out the lessons he had learned from personal experience. What might an operation be expected to do? It might (1) bring about some change in the secretion of the gland and so relieve symptoms due to disordered metabolism; (2) relieve symptoms due to the pressure of an enlarged gland upon neighbouring structures, particularly the optic nerves and chiasma; (3) relieve symptoms of increased intracranial pressure. The activities of the gland might be affected by functional disturbances of obscure origin as in acromegaly; by being the seat of hyperplasia or neoplasia; by injury; by adjacent growths, or by pressure of intra- or extra-ventricular cerebro-spinal fluid. Surgical intervention upon the function of the gland had had little success. The surgeon could do more by relieving local pressure. "Removal" in speaking of the pituitary meant partial removal. Removal then helped the symptoms. Whether "bursing" or more ordinary in type, became less marked. Simple temporal decompression relieved the intracranial pressure. The causes of failure, in his experience, were:

- 1. Errors of diagnosis leading to misguided operations.
- 2. Massive intracranial extension of the tumour rendering the case unsuitable for any operation save a palliative decompression.

resection of the ulcer and gastro-enterostomy, as opposed to pylorotomy, which he reserves for special cases. On the whole, we believe he is on solid ground here. The section on the biliary system is good, and includes an account of his own ingenious and very successful operation for repair of the common bile duct.

One of the most valuable sections of the book is that on visceroptosis. It is becoming increasingly but very gradually clear that visceroptosis is not an affection remediable by surgical means. Many devices have been sought to combat it—divisions of bands and dissections of membranes on the one hand, fixations on the other, colectomies and short circuits. All are destined to one inevitable end. There is the first deceptive improvement, eagerly looked upon by both surgeon and by patient as a cure, and then the customary relapse. This is not to say that these patients should not be explored. Medicine is not a finite subject, so that one may know always and without exception that a patient has or has not a definite disease. And once the abdomen is opened the desire to do something for one's patient leads the surgeon on to perform someone's operation or devise a new one of his own. But it is well that the temporary value of such things should be known.

Mr. Walton has covered a wide field, and that with credit to himself and to British surgery. His views are essentially sound views, and he is not led by false enthusiasms. The book, we think, might have been shorter, and perhaps in future editions Mr. Walton may ruthlessly cut it down. But to the author who is proud and jealous of his work curtailment is the hardest task of all. Medicine, too, is at a disadvantage over the arts in that a certain amount of repetition is essential. The post-graduate is a "dipper"; he does not read a book from cover to cover save rarely. And the unfortunate author has to guard himself against the attacks of his readers. There is an excellent bibliography.

#### VENEREAL DISEASE IN THE AMERICAN EXPEDITIONARY FORCES.

IN this book, *Veneral Disease in the American Expeditionary Forces*,<sup>2</sup> Dr. GEORGE WALKER, late Colonel Medical Corps, U.S.A., gives a graphic and extremely illuminating account of the various measures taken by the Urological Department of the American Armies to prevent venereal disease among the troops and to treat it when it occurred. Great reliance was placed on what the author describes as "Prophylaxis." Disinfection at a "Prophylactic" station of the individual after exposure, and self-disinfection by the man himself by means of an outfit previously supplied, are both described in this work as "Prophylaxis." Interesting statistics are furnished as to the number of times such treatments were given, and of the number of infections afterwards noted. He comes practically to the same conclusions with regard to the value of "disinfection" of both kinds as the Committee which lately sat in this country under the chairmanship of Lord Trevethin—namely, that "skilled disinfection" at a station is by far the most effectual, but that "self-disinfection" properly and promptly carried out by a well instructed and sober individual gives also a certain measure of protection. The problem which faced the Medical Department of the American forces was indeed a vast and grave one. After the first troops landed at St. Nazaire the infection rate was 240 per thousand per year among the white and 625 per thousand per year among the coloured forces. Very stringent measures were enforced. Brothels were put out of bounds, and prophylaxis (skilled disinfection) insisted on; in the case of the negroes every man on his return to camp was disinfected, whether he had been exposed to infection or not. The result was that the number of cases of disease soon diminished. At many other stations and ports the infection rate, though not as high as that just given, was high enough to cause grave anxiety. In addition to "prophylaxis," other salutary and energetic measures were

taken. First, extensive and intensive education. Secondly, places which served as rendezvous were put out of bounds. Thirdly, sources of infection were traced and removed. Fourthly, recreation and amusement for the soldiers were provided. Fifthly, means were taken to lessen the opportunities for the association of the Americans with the French population; and, sixthly, the use of alcohol was restricted. All of these measures were carried into effect as far as possible, and the final result, at the end of the war, was that though it was computed that 71 per cent. of the forces exposed themselves to the risk of infection, the case rate of venereal disease was only 35 per 1,000 per year. Many difficulties were encountered in carrying out this campaign, and also obstruction on the part of some French authorities and some American officers, but the success which rewarded the efforts made is an ample justification of the judgement of the American Urological Department. The horrible conditions obtaining in the "tolerated" houses and among the registered prostitutes are mentioned, and the periodical so-called examinations of the unfortunate women is stated to be quite useless. These examinations, as at that time conducted, were considered to be infinitely more likely to spread disease than diminish it. The chapters on treatment are full and interesting. The statistical tables throughout the book are very complete. The author also discusses the question of venereal disease in the other allied armies and the civilian population, and all he has to say on these subjects is well worth reading. It is evident that much can be done both in the way of prevention and cure when men are under discipline and the medical officers capable and energetic.

#### ASTHMA.

MR. FRANK COKE's recent book on *Asthma*<sup>3</sup> shows the change that has taken place in the etiological conception of this condition—namely, that it is the outcome of hypersensitiveness to a foreign protein—and how its modern treatment has altered in accordance with this interpretation. The therapeutic methods are indeed more novel than the etiological views, and Mr. Coke rightly quotes from Hydo Salter's remarkable book published in 1868 to show that the latest work on sensitization to animal hairs and the dermal reaction were anticipated by him. The development of the rational treatment of the affections, aptly termed the toxic idiopathies by Dr. John Freeman, has been a growth of quite recent years, and owes much to him and to I. G. Walker of Boston, Mass. Mr. Coke gives an account of the results obtained in 350 cases of asthma examined and treated on these lines, and recalls the papers by him published in our columns (1921, i, 372) and elsewhere. Although he defends his definition of asthma as "a form of dyspnoea in which the obstruction to respiration lies in and about the bronchi and bronchioles" from the objection that it is too broad, Dr. A. F. Hurst's definition, which is not quoted, as "the reaction of an over-excitable bronchial centre to blood-borne irritants and to peripheral and psychical stimuli" would appear to meet the case better. With apologies for its hybrid character, Mr. Coke suggests the new word "adzyme" to describe "some factor in the blood or tissues responsible for the process whereby an animal becomes sensitive to a foreign protein"; he thinks that it may be convenient until more definite knowledge of the whole syndrome of sensitization and anaphylaxis makes it possible to construct a better one. He imagines that when only small quantities of protein enter the body neutral adzymes deal with them, but that when larger quantities gain an entrance specific adzymes are evolved with the power of acting on or simply uniting with the protein to form a poisonous combination (anaphylatoxin) which causes anaphylaxis; it is suggested that "its method of action is rather by a colloidal change of adsorption than by a proteolytic change in the foreign protein such as can be measured against tryptic and antitryptic valencies." Anaphylaxis and asthma are compared, but the general

## NOTES ON BOOKS.

DR. BERNHARD-SMITH, in his book *Poisonous Plants of all Countries*,<sup>6</sup> gives short descriptions, accompanied by small line drawings, of the chief poisonous plants of the world. About a dozen lines are devoted to each plant and the botanical names, the common names, and the chief botanical characteristics are mentioned. We are not sure for what class of reader the book is intended; it is too small to be of much use for general reference, and the line drawings are not sufficiently detailed to be of much use for identification. The plants are classified according to their pharmacological actions under the headings of poisons acting on the brain, on the spinal cord, on the heart, irritants, and specific irritants. This classification results in henlock, Calabar bean, jaborandi, and ipecacuanha being grouped together as cardiac depressants, while aconite, laurel, and digitalis are grouped as asthenics. We suggest that an alphabetical or botanical classification would be simpler and would produce fewer surprises. Short poetical quotations under each plant are an interesting feature of the book, but unfortunately the application of many of these is rather forced, and in some instances they are perverted from their original meaning. For instance, a quotation from Swinburne's *Garden of Proserpine*, which commences

"But blooming buds of poppies,  
Green grapes of Proserpine,"

is made to serve for black bryony by the deletion of the first line.

Dr. WILHELM STEKEL's book on fetishism, for medical practitioners and criminologists,<sup>7</sup> forms the seventh instalment of an immensely long work on disturbances of the impulses and emotions, of which mention was made in the JOURNAL of April 15th, 1922 (p. 607.) The characteristic traits of fetishism are said to be the suppression of active sexuality in both sexes, psycho-sexual infantilism, and in most cases a disposition to accumulate large numbers of his fetish (articles of clothing, hair, flowers, etc.). A tendency to experience again certain infantile pleasures leads to fugues, kleptomania, and exhibitionism. Fetishism is regarded as a compulsion neurosis, which also gratifies the subject's ascetic tendencies. The impulsive actions are carried out in a sort of twilight state, and the fetishist is a day dreamer who fails to realize the differences between reality and dreams. In all cases there is a criminal element (sadism). After all this and much more, it is not surprising to be told that the symbolism of fetishism can only be explained by psycho-analysis. The book contains lengthy descriptions of cases from the practice of the writer and others, some of whom seem to be called sexuologists. How many persons will set out to read this work and how many who make the attempt will thereby be benefited are matters on which we will not speculate.

Since Jules Verne novelists have rather eschewed scientific sensations, but so much has been published in the daily papers about the prodigious store of energy that would be set free by the disruption of the atom that the shrewd reader will make a guess that it provides the plot of a novel entitled *Atoms*,<sup>8</sup> by T. C. WIGNALL and G. D. KNOX. The idea is worked out ingeniously and the possible consequences described in sufficiently lurid colours to satisfy the most insatiate lover of sensation; if the authors have to indulge in some didactic conversations they contrive a thrill in every chapter, and each thrill is skilfully made to arise out of the astonishing speculations and calculations of modern physicists. It is a good book for an idle afternoon, and the reader will be relieved that the worst did not happen.

## BEIT MEMORIAL FELLOWSHIPS.

THE following have been elected to Beit Memorial Fellowships:

Senior Fellowship, value £600 per annum: Dr. David Keilin, fourth year Fellow working under Professor G. H. Nuttall, F.R.S., at the Molteno Institute for Research in Parasitology, University of Cambridge, on the life-history of parasitic protista and on the physiology of parasitic metazoa.

Fourth Year Fellowship, value £400 per annum: Miss Katherine Hope Coward, D.Sc., now working at the Biochemical Laboratory, Institute of Physiology, University College, University of London,

on an investigation into the process of metabolism, nutrition and growth of young animals, particularly with reference to so-called deficiency diseases, such as rickets.

In view of the high attainments of the candidates for junior fellowships the trustees decided to award ten fellowships instead of six, and the following were the successful candidates:

John Maurice Hardman Campbell, Senior Demonstrator of Physiology at Guy's Hospital.

Charles George Lambie, Lecturer in Clinical Medicine, Edinburgh University, and Assistant Physician to the Royal Infirmary, Edinburgh.

William Kershaw Slater, who is in receipt of a grant from the Medical Research Council for research work on the heat of combustion of glycogen.

Dorothy Stuart Russell, Pathological Assistant, London Hospital, Corbet Page Stewart, University Assistant in Medical Chemistry, Edinburgh University.

Harold John Channon, engaged on the study of certain fundamental dietary factors in the nutrition of living organisms.

William Smith, Junior Demonstrator in Biochemistry Classes, Cambridge University.

Lewis Bland Winter, Junior Demonstrator in Biochemistry Classes, Cambridge University.

Dorothy Beatty Steabben, Demonstrator in Physiology and Histology at King's College, London.

Cedre Stanton Hicks, Otago University, New Zealand, Public Analyst for Otago and Southland Provinces, and Chemical Pathologist and Assistant General Pathologist, Otago Medical School.

## MEDICAL AND SURGICAL APPLIANCES.

## A Resetting Case for Clinical Thermometers.

MESSRS. G. H. ZEAL, LTD., of 77, St. John Street, E.C.1, manufacturers of thermometers, have produced a resetting case for clinical thermometers to which they have given the name *Acello*. It is an ingenious little instrument, larger than the ordinary thermometer case, but small enough to go into the waistcoat pocket. The case containing the thermometer can be revolved rapidly between a small swivel handle held by the fingers of one hand, and a long handle, working on a screw shaft jointed to the case, held by the fingers of the other hand. The instrument will easily reset the most obstinate thermometer, and is likely to be useful especially to a patient who has to take his own temperature. The price is 2s. 6d.

## Urethral Bougies.

MR. BERNARD WARD, F.R.C.S. (Consulting Surgeon, Queen's Hospital, Birmingham), writes: For several years past I have used with advantage urethral bougies considerably shorter in the beak than those usually employed, and Messrs. Arnold and Sons, of 50-52, Wigmore Street, W.1, have recently made some for me. They have a short beak; are graduated from the point to the convexity

of the curve in English, and in the corresponding Charrière scale. The advantage of these bougies is that in the ordinary treatment of a stricture I find they are more easily passed than the usual type. It is rarely necessary to pass them so far that the tip of the bougie goes beyond the membranous urethra; the advantage of this will be at once obvious. The same firm have also made for me a set of bougies with a *Benique* curve, which are also much shorter in the beak than the usual pattern. In use I find them extremely satisfactory.

## An Aid to Ophthalmoscopy.

DR. D. N. HARDCASTLE (Bushey) writes: Last year, after having used an ordinary electric ophthalmoscope for some time, I found that if the light was sufficiently powerful to see the disc in an ordinary room, there was a haze round the spot in the mirror and also from the transverse beam. I tried various forms of mirrors—glass, steel, and silver—but could not obviate this haze and back light from the spot. I then tried building a small hood round the spot, but found this interfered somewhat with the vision. As a last resort I decided to try a glass prism slotted. Messrs. George Spiller, Ltd., have produced a small silvered prism with a slot for vision, and with this have made an ophthalmoscope from which there is no back light or haze, so that the light can now be much stronger and a good view of the disc obtained in full daylight.

## A Two-Loop Bufton Suture.

DR. J. B. PIKE (Loughborough) writes: In the JOURNAL of June 9th, p. 969, I saw a description of a button suture to include two layers of tissue. In June, 1906, I described and illustrated in the *Lancet* a double-loop suture with a similar object, and I think somewhat simpler. It was stated at the time that the method had been used in Australia and by Professor Senn of Chicago. The only English surgeon who has mentioned the use of this suture is Mr. Sampson Handley. Personally I have often found it useful.

the Vice-Chancellor and President of the College; to Dr. J. A. Lindsay, M.D., F.R.C.P. Lond., Professor of Medicine; and Mr. Thos. Sinclair, M.D., F.R.C.S. Eng., Professor of Surgery.

tesor of Surgery, all of whom were now retiring; and whose loss to the University was deeply and widely felt. They had all served the College and University in their several capacities with devotion and distinction. As regards

the pursuit of learning for its own sake was emphasized and hardly be exaggerated. The value of research at an independent university is the importance of a busy commercial centre such as Belfast. In the midst of a busy commercial centre such State interference or control was very much to be deprecated. In the midst of a busy commercial centre such must be preserved, and that anything in the nature of interference or control was very much to be deprecated. In the midst of a busy commercial centre such

The Chancellor, the Speaker of the House of Commons of Northern Ireland (the Right Hon. Hugh O'Neill), and Sir Havelock Charles, Seigneur-Surgeon to H.M. the King, received honorary degrees of L.D., which were conferred by Sir Samuel Dill, Pro-Chancellor. Some seventy-six candidates received the M.B. degree.

Meeting of Core Medical Practitioners.—At a meeting of Core medical practitioners the following and gratitude for their delightful and well-earned hospitality. (After Constabulary, and the hosts gained the warm thanks. (An excellent music was given by the band of the Royal (Something was done to provide for their comfort and enjoyment. (Honorary graduates. (1) That the committee of Cork medical profession protest against the Government introducing any medical legislation with-out consulting the elected representatives of the Irish medical profession.

(2) That the committee strongly support the Irish Medical Committee in any action they may take in this matter.

INSURANCE IN GENERAL PRACTICE.

Sir, I do not think the medical profession realize as yet the full economic possibilities of insulin.

The consensus of expert opinion seems to be that its usefulness is confined to tiding patients over such crises as many arise, and that on account of its cost its continued use is only for the very rich or the very poor. That perhaps it is likely to be so correlated with the very poor.

the blood sugar never rose above 100 mg per 100 ml. The blood sugar was even below normal before the operation. The maximum per day consumption of insulin was 20 units minimum per day. After the operation they could consume 10 to 15 units per day and the blood sugar was normal. The patient was discharged 5 days after the operation.

The result of the experiments has been surprising. All patients have gained weight, have resumed work, or where they were working short time are now working full time. It was clearly proven that a normal blood sugar is not necessary for an amelioration of diabetes and that a normal blood sugar is not such as polyuria, thirst, lassitude, neuritis, and nervousness.

Case X. Y. Man aged 34. Symptoms—thirst, dry mouth, polyuria, and neuritis so severe that for the past seven years he has slept with his feet stuck out from under the bedclothes and has had a nightly dose of morphine. For the past 3 years he has had 10 mgm. of insulin before breakfast and before the evening meal. 1.35 am. before breakfast his blood sugar is 0.9, falling 15 minutes after breakfast it is 0.2, one hour after breakfast it is 0.1.

*Education and After-Care.*

Passing next to the therapeutic aspect of the educational methods employed at Alton, Sir Clifford said:

"At Alton education means a drawing out of all the latent faculties of the patient, an experience that in itself, apart from the manner of doing it, is life and joy; a reanimation of body as well as of mind. As somebody said, 'What is the good of an airy house if you have a stuffy mind!' Now we are all materialists enough to admit that mind and body cannot be separated; that one cannot exist without the other; a pianist without a piano is a pianist no more. By mental activity the body also is aroused; higher spirits begin to course along the veins; affections are warmed; hope returns, and the little sufferer begins to feel that at last he too is somebody. Great is the medicine of happiness. It seems probable that not only is the nervous system thus aroused, but also that our wireless endocrine system submits to influences which in the organic life are no less powerful.

"In two ways the work at Alton may be aided: first, by sending early cases, and second, by following up patients after discharge, that the permanence of the cure may be attested and any tendency to relapse checked in time. There are good grounds for hoping that the cures may number 95 per cent. And I would add—let us see that the return home may not be to bad conditions of life, such as probably ministered to the disease; to insufficient food, insanitary houses, low habits of life, and so forth. Greatly to amend these conditions is beyond our individual efforts; but we may do, each one of us, a little by incessantly pressing these needs upon the minds of the leaders of the nation. Indeed, we need not be despondent; much has been done already, although much more lies on the public conscience for future harvesting. . . . And in speaking especially of Alton, may I play on an old string of mine, nay on two: First, may I rejoice in the remarriage of surgery and internal medicine, the divorce of which has been one of the chief banes of Medicine during long periods of its history; and secondly, on the establishment at last in my own university of an Institute for Comparative Medicine in which the study of the diseases of many kinds of animals will throw mutual lights upon those of each; as you know tuberculosis is a disease common to man and many animals."

*THE CLIMATE AND REST METHOD.*

A warm vote of thanks was accorded to Sir Clifford Allbutt, on the motion of the Medical Superintendent, Sir HENRY GAUVAIN, and the visitors then went on a tour of inspection of the wards and other departments of the hospital. The afternoon was fine, and a very large proportion of the children were receiving the open-air and sun treatment on the balconies which communicate with the wards. Care is taken by the use of movable screens, and in other ways, to avoid blistering; and, by means of such occupations as basket-making, the children's minds are diverted from the fact that they are undergoing a course of treatment. Constant attention to detail is needed in carrying out this form of conservative therapy, both general and local, which may be described in brief as the "climate and rest method." Besides the treatment and education of its child patients, the institution gives technical training in workshops to crippled lads between the ages of 14 and 18 for whom nothing further can be done medically. The majority of the children under treatment are cases of tuberculous hip disease; those with active spinal caries are nursed on special stands designed and made on the premises. An interesting part of the hospital is the plaster room and splint department; nearly 1,000 non-inflammable celluloid splints are put up in the course of each year. One ward in each of the two fan-shaped medical blocks is set apart as an observation ward, where every new patient on admission is kept in quarantine in a separate cubicle for at least a fortnight. During this period the patient is fully investigated, medically and from the educational aspect, and splints are prepared.

The bright eyes, bronzed skin, and firm flesh of these children speak eloquently in favour of the sun cure when judiciously applied in appropriate cases. Every kind and degree of pigmentation can be observed on their bodies as they lie out in the sunshine, naked but for a sun-hat, a loin-cloth, and (in most cases) a splint.

Members of the British Medical Association attending the Annual Meeting next week at Portsmouth will have opportunities of visiting both the Cripples' Home at Alton and the associated Hayling Island Sanatorium.

**NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.***CONFERENCE IN BIRMINGHAM.*

The opening session of the Ninth Annual Conference of the National Association for the Prevention of Tuberculosis was held in the University of Birmingham on July 12th, and in spite of the torrid atmosphere there was a crowded and, as events turned out, an enthusiastic meeting. The delegates were welcomed by the Lord Mayor of Birmingham (Sir David Davis), who referred with justifiable pride to the part played by the city he represented in the campaign against tuberculosis. The Hon. Sir ARTHUR STANLEY, who presided, thanked the Lord Mayor on behalf of the association and commented in a few happily chosen sentences on the high civic spirit of Birmingham.

*Care of Advanced Cases.*

The subject down for discussion was the care of advanced cases of tuberculosis, especially with regard to the prevention of infection. In the absence of Dr. William Robertson, M.O.H. for the City of Edinburgh, who was to have initiated the discussion, his contribution was read by Mr. JOHN ROBERTSON, M.O.H. for Birmingham. The author of the paper hazarded the view that the segregation of advanced cases of pulmonary tuberculosis was quite as important in its way as the isolation of a case of small-pox, and in dealing with the problems offered by the incorrigible "in-and-out" tuberculous subject, who, after a short period passed in an institution, insisted on leaving and returning to his home, where he was a grave potential danger to his friends, suggested that the use of more drastic measures for compulsory detention should be exercised by the sanitary authorities. He further emphasized the need for a more thorough system of disinfection of the rooms occupied by such a person. Housing was the *alpha* of the tuberculosis problem, but the disposal of the advanced cases constituted its *omega*.

Dr. F. N. KAY MENZIES (London County Council) questioned whether institutional segregation was the best policy, and further suggested that exaggerated statements had been made as to the infectivity of the disease. He thought that if the impression was given that the responsible authorities considered that the infectivity of tuberculosis was little less than that of small-pox, it might create difficulties in administration, and especially with regard to after-care work. In his view home segregation should be first considered, and, in default of this only, institutional segregation. The main consideration was the avoidance of the infection of children. He regarded food and not housing as the *alpha* of the tuberculosis problem.

Professor S. LYLE CUMMINS, who followed, emphasized the danger of infection. Every case of pulmonary tuberculosis had at one time been infected, although this might have been years before the development of the disease. The chronic fibroid type of advanced case, often only seemingly showing evidence of chronic bronchitis or asthma, was the most dangerous from the point of view of infection. In an inquiry undertaken by the medical staff of the Welsh National Memorial Association recently, 51 per cent. of 354 female cases and 33 per cent. of 268 males had a history of definite contact with such cases in their homes. He did not, however, believe in compulsory segregation. We still know too little about the disease and must endow research more generously than at present.

In the opinion of Dr. DAVISON (Assistant M.O.H. Birmingham) any such preventive measures as had been suggested must first be acceptable to the public. He was in favour of encouraging segregation in the home after a period of educational treatment in a sanatorium, as being the most humane method. There were many young adults in full work quite as dangerous sources of infection as the typical advanced case.

Some characteristic points were made by Dr. MARCUS PATERSON. He referred to the type of tuberculous person who not only made no attempt to follow advice given; but was often in fact wilfully harmful. These cases should be taken before a magistrate and certified as a danger to the community like any ordinary lunatic. There were several

[illegible]

I have been a member of the Royal Society of Medicine since 1891, and have been a member of the Royal Society of Medicine since 1891. In the first attack he was ill for over twenty-five days and had a history of cough, which continued for over ten days after the fall of temperature. He was not able to get up and had to be carried to bed. He had no fever and no other symptoms. He was not able to get up and had to be carried to bed. He had no fever and no other symptoms. He was not able to get up and had to be carried to bed. He had no fever and no other symptoms.

(a) those giving rise to anaemia and gastritis; (b) those affecting the respiratory tract, of which tuberculosis was the more prevalent. If the injurious effects of this trade were to be reduced to a minimum, adequate methods of ventilation must be utilized and provision made for the rapid removal of dust. Bathing facilities might be made available for the men after leaving work, and it was of some importance that the amount of clothing worn should be increased on coming into a cooler atmosphere. More temperate habits were also desirable among this class of worker.

Mr. G. A. ISAACS, of the National Society of Operative Printers and Assistants, also contributed some valuable information to the discussion from the point of view of the interested layman. He refuted the popular view that compositors were more seriously affected by tuberculosis than any other branch of the printing trade, and quoted the result of an inquiry by the late Professor Benjamin Moore which showed that in the case of printers' assistants nearly one-half of all deaths were due to phthisis even at the present time. He considered that there were more deaths due to tuberculosis than the death certificates would indicate. With regard to the conditions under which machine-room work was carried on, these had considerably improved, but much had still to be done, and better wages had resulted in a great improvement in the physical condition of the workers. He asked for the co-operation of the medical profession in making the printing trade at least as healthy as other trades. Dr. SCURFIELD put in a plea for the breaking up of the tuberculosis death-rate into its component parts in order that the nature and extent of the problem of prevention as affecting various localities might be more clearly recognized.

Dr. J. DOUG MCCRINDLE (Chief Tuberculosis Officer, Northampton) took up the discussion in connexion with the boot industry. He gave an interesting résumé of the processes of bootmaking which threw some light upon the prevalence of tuberculosis among boot and shoe workers. Apart from its sedentary character, there seemed to be nothing intrinsically detrimental to health in this occupation, but the close proximity of the operatives to one another, and the frequently imperfect ventilation and lighting, were no doubt contributory causes in the high incidence of tuberculosis in this industry. The boot worker suffering from tuberculosis should, when the disease had been arrested as the result of treatment at a sanatorium, be given the opportunity of resuming his own work under the graduated labour system.

#### *Notification of Tuberculosis.*

The afternoon session, which met under the presidency of Sir ROBERT PHILIP in the unavoidable absence of Sir Arthur Stanley, dealt with the question of the "Notification of Tuberculosis," the discussion being opened by Dr. G. LISSANT COX (Central Tuberculosis Officer, Lancashire County Council). He was of opinion that while the Tuberculosis Regulations were admirably drawn up from an academic point of view and provided for every contingency if properly carried out, in actual practice some of the provisions had given rise to misconception with unfortunate results to the public health. Article V of the Regulations appeared to call for amendment more than any other. The profession should be encouraged to notify every case occurring in practice, even at the expense of duplication of notification. Further, as suggested by Dr. Dudfield, the medical practitioner should repeat his notification if the patient moved into a new district and the same practitioner remained in attendance. A large proportion of notified cases were too frequently in a late stage of the disease when notification was carried out, many of them having had no medical attendance until this stage had been reached. On the other hand, there did not appear to be any large number of cases of unreasonable delay by the doctors in referring cases to the tuberculosis officer. The further education of the public as to the symptoms and dangers of tuberculosis and the need for seeking advice early was urgently called for. The general practitioner should be encouraged to refer all doubtful or early cases to the tuberculosis officer. It was now possible, with the con-

currence of the notifying practitioner, to have cancellation of any case wrongly notified as tuberculosis.

Dr. DUFFIELD (Administrative Tuberculosis Officer, Paddington) followed, and said that Dr. Cox had anticipated his remarks for the most part. He said it was a disappointing fact that compulsory notification of tuberculosis had not achieved the success hoped for. Not only was notification incomplete, but too many certificates were received too late. The proportion of deaths from pulmonary tuberculosis representing fatal terminations of cases not known to him before death had occurred had notably increased. There had of late, however, been some improvement in the notification of non-pulmonary tuberculosis. Articles V and VII of the Regulations both needed amendment. The administrative difficulties which often arose when patients left the district in which they had originally been notified and had refrained from seeking advice in their new homes might be overcome by friendly sympathy and tactfulness on the part of tuberculosis visitors or nurses.

In the opinion of Dr. A. S. M. MACNEGON (Public Health Department, Glasgow) efficient notification depended upon an efficient tuberculosis service, and the provision of proper treatment was dependent upon promptitude of notification. He thought that our diagnostic service was not so efficient as it might be. Diagnosis and the facilities for this should be in the forefront of any tuberculosis scheme. There was a danger that the tuberculosis officer might develop a bias towards the diagnosis of pulmonary tuberculosis when the patient was not really suffering from this but from some other chest affection. The tuberculosis service had not been free from criticism in this respect.

Dr. CECIL WALL (Physician to the London Hospital and to Brompton Hospital) suggested that the ideal to be aimed at should be the notification not only of undoubted cases of tuberculosis but of suspected cases, and that the printed form should be so amended to allow of this being done. Notification should be repeated at intervals of six months if the patient was still under treatment. He further thought that there should be a clearing-house or bureau for the whole country.

The proceedings closed with a hearty vote of thanks to the Lord Mayor of Birmingham, and to Dr. John Robertson for his invaluable assistance, which contributed so much to making the present Conference one of the most successful ever held by the National Association.

As a fitting pendant to the work of the Conference, a public address on "The Actual Position of the Tuberculosis Problem To-day" was delivered by Professor Sir ROBERT PHILIP on the evening of the second day, in the Midland Institute, to a large and appreciative audience.

### THE NATIONAL PROVIDENT ASSOCIATION FOR HOSPITAL AND ADDITIONAL MEDICAL SERVICES.

IN the SUPPLEMENT of April 20th, 1921, page 161, was published a scheme for the provision of hospital and other medical services drafted by the Council of the Metropolitan Counties Branch, and based upon what is known as the Sussex scheme. Under the title "The National Provident Association for Hospital and Additional Medical Services" the scheme then outlined took shape in London in November, 1921; and we have now received a report by the executive committee covering the period from November 1st, 1921, to February 28th, 1923. The report is signed by Sir Arthur Stanley, Lord Dawson, Mr. W. McAdam Eccles, Sir Alan Garrett Anderson, and Dr. J. F. Gordon Dill, and is as follows:

The National Provident Association for Hospital and Additional Medical Services, by arrangement with the several interests concerned, was established in London on November 1st, 1921, and £55 was spent in a few newspaper advertisements. When 2,315 members were rapidly enrolled it was decided to treat the first year's working as an experiment, and not seek further members until the Association was incorporated and put on a permanent basis. The amount received in subscriptions was £1,770.

The object of the Association was to induce people while in health to make provision for the time of serious illness and to enable its members to obtain such services other than ordinary

### ANTLERS AND BONE GROWTH.

IN these days of specialization, when the minds of men are absorbed by the study of sharply defined and particularized problems, it is inspiring to be confronted with one who grapples with things on the grand scale. We live in an age which is shy of generalizations, and truly the comprehensive reasoner often leaves himself open to attack. No one can deny the charm of these wide conceptions, but in order that they may bring us profit they must be propounded by one of great austerity and purity of mind. In his last book the late W. H. Hudson describes how he watched a hind in Richmond Park. The animal lay listening for a long time to sounds issuing apparently from a wood some distance away, sounds which were of the greatest interest to it, yet none of them appreciable to the human ear. The behaviour of the deer furnishes Hudson with material for a leisurely discussion on the nature of hearing in animals, vague and nebulous often, but always delightful in his charming prose.

Sir William Macewen, in his presidential address to the Société Internationale de Chirurgie, also takes the deer as his subject, and uses the growth of the antler to illustrate his views on the formation of bone. Now if we compare these two generalizations, or rather these men who made them, we find Hudson with a great reputation as a naturalist. If his reputation rested on that alone it is unlikely that he would be long remembered, for though he was a keen and accurate observer of birds and animals all his life, his was not a coldly scientific mind. He believed, for instance, in maternal impressions; he believed that the appreciation of smells and scent depended on the solution of the substance in the fluids of the nose. He believed, that is, that the odoriferous substance was a solid, in infinitely fine suspension perhaps, and that this, dissolved in the mucus of the upper olfactory passages, gave the necessary stimulus to the rhinencephalon. To put the matter thus prosaically is the absolute negation of Hudsonism. Hudson would never have dreamed of using such language, and we should have been the poorer had he done so. When we turn from him to Sir William Macewen we realize a different texture of mind altogether—a different standard. Macewen's work bears the stamp of the Royal Society; Hudson's resembles a popular lecture at the Royal Institution. And Macewen's Royal Society is the Royal Society of days when men were concerned with the wide problems of human origin and variation rather than with minute and specialized questions—with broad principles rather than with special corners of the animal kingdom. And if we must date it, it is interesting to know that the acknowledgement of the receipt of Sir William's first communication to the Royal Society on the restoration of the humerus by bone grafting was signed by Huxley.

Like all important discoveries, the study of the antler as the means of disclosing the general principles of the growth of bone is so obviously the simple and right way that one wonders that we had to wait

184 years—from Duhamel to Macewen. The meaning of the antler has always been an interesting problem. Darwin was puzzled to account for it. The rapid growth, the subsequent shedding after so short a period of wearing, the cumbrous nature of the mature structure, all present their problems and discrepancies. As an instrument of offence against any animal save one similarly armed the antler is not well planned. And there is reason to believe that the animal's sharp forefeet are much more deadly weapons. The deer's chief asset is its speed, that it may live to fight another day.

It is good to know that a thing which has troubled so many minds has been so largely the means of solving an important problem. Sir William Macewen's work on the osteoblast as "the one and only begetter" of bone has very largely proved itself. It was in the antler of the deer that he first saw the mature osteoblast conclusively. It has since been found in growing bone generally. He believes that it is a definite cell, recognizable on morphological grounds, and not merely, like a mouse in the wainscot, recognizable by the things it does.

In his present address he shows us how far-reaching in its effects is his conception of the formation of bone, but especially how elusive is the factor behind it all—the something which controls that growth. It is evident that the osteoblasts on the diaphyseal and epiphyseal sides of the cartilaginous plate in growing bone have somewhat different functions to perform, and those in the centre of the shaft something different again. Now what gave these their characters? Are they inherited? Must we, as the anatomists are so fond of saying, go further and further back? And why is the reparative function of the flat bones of the calvarium so limited? Sir William Macewen suggests the reason; but what is the cause? Is reason here synonymous with cause? Sir William Macewen recognizes in the bone cells hereditary specialism to type. He speaks of "the thousand memories of the atoms comprising each osteoblast." The doctrine he inculcates obviously has a very important bearing, not only on surgical pathology, but also on physiology and histological anatomy. Those who are working in the special fields of reparative and (as they hope) constructive surgery stand in need of these gentle reminders. They will show their worth by the manner in which they respond.

"The proper study of mankind is man," said Pope. But we shall do well to continue to take this not too literally. Of the many problems which await solution we shall gain much in knowledge and much more in wisdom by taking the wide view, in comparative physiology and pathology no less than in anatomy.

### THE WORK AND FINANCES OF VOLUNTARY HOSPITALS.

THE voluntary hospitals during the last few years have been experiencing some of the vicissitudes which are apt to occur in the careers of institutions, and individuals—such as politicians—dependent on public favour. During the war the British public admired the readiness of the voluntary hospitals to use their resources for the benefit of the wounded soldier, and positively blushed to possess establishments so efficient. In the reaction after the war the discovery that the hospitals were short of money perturbed the mind of the general public, always disposed to judge the impecunious harshly, and greatly pleased the

The series of post-graduate lectures at Queen's College, Tying-in Hospital, Marylebone, came to an end on July 19th. A new series will begin in October.

The foundation stone of the new casualty department of The Royal Northern Hospital, Holloway, was laid by Lady Patricia Ramsey on July 12th. The building is being erected by the Borough of Islington War Memorial to commemorate the supreme sacrifice of those who fell in the great war and the brave deeds of those who survived. The sum raised was about £12,600, and £2,900 more is required to complete the memorial.

The annual report for 1922-23 of the Professional Classes Aid Council (in which the British Medical Association is represented by Dr. G. E. Hall) shows that the work of the Council in assisting in relieving distress among the professional and educated classes and their dependants has been steadily consolidated during the past twelve months. During the year there were 558 new applications for whom £49 were refused as being unsatisfactory or not within the scope of the Council, and 83 former applicants reappplied (of whom 32 were refused for similar reasons). Fifty families received educational assistance during the year. The question of providing funds is still serious; the expenditure for the year amounted to £7,324, the balance sheet showing a deficit of £2,415.

PROFESSOR LUBANSECH has been appointed director of the Robert Koch Foundation for Combating Tuberculosis in place of Dr. G. E. Hall.

The death occurred at Ranton on June 27th of Dr. Edward Liddon, in his 53rd year. He was educated at King's College, London, Edinburgh University, and Paris; he took the diplomas of M.R.C.S. Eng. in 1852 and L.S.A. in 1853, and graduated M.D. Edin. with gold medal for thesis, in 1857. At the time of his death he was consulting physician to the Tannum and Somerset Hospital, of which institution he was also an ex-president and the oldest life governor. As a young man Dr. Liddon was assistant-surgeon to the Bath United Hospital and resident assistant to the Brompton Hospital. He served for many years with the 2nd Volunteer Battalion Somerset Light Infantry, retiring with the rank of Surgeon Lieutenant-Colonel. A keen sportsman all his life, he was at one time master of the Tannum Vale Hares, and hunted with them until he was over 80. Dr. Liddon was a zealous churchman—his brother was the late Canon Liddon—and a generous supporter of every philanthropic organization in his district. He was twice married, and leaves a widow and two sons, one of whom is vicar of Minehead.

Wiederholungs.

THE last week of November, President of the Royal Society of Arts, just week presented the Albert Medals of the Society, awarded to Sir David Bruce and Sir Ronald Ross "in recognition of the eminent services they have rendered to the economic development of the world by their achievements in biological research and the study of tropical diseases."

The London Hospital for Women was held on July 20th at the South London Hospital for Women. After tea in the grounds of the hospital, those who were unhampered by ill health or other engagements took part in a tour of inspection by Miss Ward and Mr. Chabourn, the senior surgeon, who played a prominent part in the foundation of the hospital in 1912 and in the planning of the building. Notable features are the provision of accommodation in small rooms and cubicles for private patients at fees varying from 3 to 6 guineas a week and the wide balconies attached to nearly every ward. A visit was paid by certain members of the theatre, where Miss Eleanor Davies-Colley was operating, and in other departments of the hospital cases and specimens were shown. A business meeting of the association in the hospital board room concluded the proceedings.

During the International Exhibition of Hygiene a general fever congress will be held at Strasbourg from August 1st to 4th under the presidency of Professor Bay of Paris. The following papers will be read: (1) Historical sketch of puerperal fever and the importance of Pasteur's discovery, by Dr. Coenavelet of Paris; (2) bacteriology and morbid anatomy of puerperal fever, by Dr. Brown of Liège; (3) diagnosis and prophylaxis of puerperal fever, by Dr. Hanch of Copenhagen; (4) treatment of puerperal fever, by Dr. Albert of Paris. The subscription is 40 francs, which includes admission to all parts of the Exhibition of Hygiene. Further information can be obtained from the general secretary, Professor Schickel, Clinique d'accouchement, Strasbourg.

A FRENCHMAN accused the English of taking their pleasure in "pleasant" games as to be included in the accusation had little truth in it until this pleasant generation, which under the pressure of American excellence is studying and playing games with astonishing seriousness. We are informed that this seriousness is now to be extended to mountain climbing. A ten-day course of scientific instruction, theoretical and practical, in mountaineering is, we are told, to be given at the end of July at Kloster, in the Grisons district, Switzerland, at a fee, including board, of 6 francs. The course is to include first aid in accidents. Full particulars may be had from Gustav Wally, Klosters. The house and library of the Royal Society of Medicine, 1, Wimpole Street, W. 1, will be closed for cleaning and repairs during the whole of August.

visitors will be presided over by Professor H. H. Newwood. In reporting on two years' working at the United States Prohibition Act, the Federal Prohibition Commissioner makes special reference to the Treasury decision, first suggested by the American Medical Association, which limits withdrawals of whisky for medicinal use to spirit which has been bottled in bond. In 1920 the total whisky withdrawals amounted to 12,389,659 gallons; in 1921, to 3,243,845 gallons; and in 1922, to 1,819,888 gallons.

During the year 1922, 9,935 cases of small-pox occurred in Canada and the United States, of which 493, or 5 per cent, were fatal. In 1921 the mortality was only 1 per cent. In some towns the case mortality during 1922 ranged from 16 to 85 per cent.

VISCOUNT BURNHAM has accepted the office of Vice-President of the Royal Sanitary Institute, which was founded in 1876, and has for over thirty years maintained a name in sanitary apparatus. The institute will hold its thirty-fourth congress and health exhibition at Hull, beginning on July 30th. The Right Hon. T. R. Fernald, High Steward of Hull, will preside, and nearly 500 delegates have been appointed from this country, including those nominated by the Admiralty, the Board of Control, and the Office of Works; the War Office, the Ministry of Health, and the Scottish Board of Health. Representatives have also been nominated by foreign and dominion governments, and municipalities, including Bombay, South Australia, New South Wales, Victoria, Kimberley, Perth, New Zealand, Christchurch, Cape Town, Transvaal, South Africa, Czechoslovakia, Greece, Mexico, U.S.A., will give a lecture on a pure water supply to the United States of America. Sir Alexander Houston, K.B.E., M.B., will give a lecture on Tuesday, and on Thursday, August 2nd, Mr. B. Seebach-Kornmeier will give a popular lecture on industry and national welfare. There will be four sections: sanitary science, of which Sir William Hamer, M.D., is president; maternity and child welfare, including school hygiene, presided over by Dr. J. R. Kaye; engineering and architecture; and domestic hygiene. There will be seven conferences: one of medical officers of health will have Dr. Eustace Hill as chairman, and another on health.

the Grand Council of the Campaign held on July 16th the principle of appointing a scientific advisory committee was accepted, and that apparently it has gone further than this and has proposed that the committee shall consist of ten persons—five to be nominated by the Royal Society and the Medical Research Council jointly, and five by the Grand Council. Whether the suggestion will be acceptable to the Royal Society and the Medical Research Council we have no means of knowing. The report presented to the annual meeting of the Imperial Cancer Research Fund on July 17th contained a summary account of the negotiations that have been going on since April between the Fund and the promoters of the Campaign. It was laid down that the complete independence and individuality of the Fund must be maintained, and that it could not associate itself with the Campaign unless other cancer research institutes were invited to take part and assured of receiving financial support. The result of an interview in May with Mr. G. Locker-Lampson, M.P., Honorary Secretary of the Committee of the Campaign, was not deemed satisfactory, and it was then decided that it would be inadvisable for the Fund to participate in the campaign. Since then the executive of the Fund has been informed that the promoters of the Campaign have recognized the necessity of modifying its articles of association. Speaking at the meeting on July 17th the Duke of Bedford, President of the Fund, said that the modifications proposed included the appointment of an Advisory Committee which it is hoped will comprise members nominated jointly by the Royal Society and by the Medical Research Council. "In the event of these modifications being carried out," the President continued, "they would, I think, secure the confidence and co-operation of bodies, including the Imperial Cancer Research Fund, which have been for many years past engaged in the work of cancer research, because in their opinion the future administration of the British Empire Cancer Campaign would then be guided by those whose knowledge would enable the best use to be made of all funds available. It is therefore obvious that the adhesion of this Fund to the British Empire Cancer Campaign must be dependent upon the decision of our Executive Committee when the revised articles of association in their final form have been fully considered. It is very certain from letters and articles which appear from time to time in the press that incredibly little is known of the work that has already been done by our Fund and by other research bodies, both in this country and in the rest of the world—for instance, the information collected by the Imperial Cancer Research Fund relating to cancer in native races throughout the Empire, and of its occurrence in all species of the animal kingdom. For this reason it would seem to be essential that the administration of the funds of the Campaign should be in the hands of those who know what experimental work has already been done, and what information on the subject has already been accumulated. By these means useless repetitions would be avoided and public money used to the best advantage. The annual report of the Imperial Cancer Research Fund shows that it has continued to pursue its considered policy of co-operation in the free and friendly intercourse between the workers in different laboratories, coupled with the interchange of material. In conclusion let me add that I believe that such co-operation and co-ordination must be voluntary. It cannot be forced on the workers."

#### TREATMENT OF LEPERS.

VISCOUNT CHELMSFORD presided at a meeting held at the India Office on July 12th, when it was decided to form a British Empire Leprosy Relief Association. It was stated that the British Empire has more known lepers than

any other political entity in the world, but is doing far less in proportion than is being done by the United States for its lepers. Less than 5 per cent. of the sufferers in the King's dominions, it was reported, are being cared for in any way, and of these, owing mainly to the poverty of the countries most affected—namely, India, tropical Africa, and the West Indies—only a small proportion are receiving the treatment by derivatives of chaulmoogra and certain other oils which has been used with so much success during the last eight or nine years. A general committee was appointed, which includes Lord Chelmsford, Lord Ronaldshay, Lord Riddell, Sir Humphry Rolleston, Sir William Loishman, Sir Havelock Charles, Sir Clifford Allbutt, Sir Archibald Garrod, Sir George Newman, Sir John Rosa Bradford, Sir Walter Fletcher, Sir Malcolm Morris, Sir George Berry, M.P., Dr. F. E. Fremantle, M.P., Sir William Edwards, Sir Edward Gait (Member of Council, India Office), Sir William Vincent, Sir Charles McLeod, Sir Rajendranath Mookerjee, Sir Frank Carter, Sir James Michelli, Sir Leonard Rogers, Professor J. J. W. Stephens, Lieut.-Colonel A. Alcock, Lieut.-Colonel S. P. James, Dr. Andrew Balfour, Mr. H. S. Wellcome, Dr. Cochrane, and Mr. F. Oldrieve. An executive committee and subcommittees were appointed to prepare plans for carrying out the objects of the association.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual dinner of the Medico-Psychological Association on July 11th must surely have established a record, at any rate for this country, in the number of speeches—sixteen—accompanying the various toasts. Dr. Edwin Goodall, president of the association, was in the chair, and was in his happiest vein in proposing the health of the sister societies. He described a medical society as a conventicle where the older members of the profession assembled to drink in wisdom from the lips of their juniors. More seriously, a society was a means of exchanging medical experience, exposing new lines of research, presenting new facts, and promoting good manners among the followers of a profession who in their daily work sometimes indulged in asperities with regard to one another. He recited a formidable list of the medical societies now existing in London, and made a good deal of play at the expense of that "hydra-headed monster" the Royal Society of Medicine, against whose absorptive capacities, however, he was glad that the Medico-Psychological Association had remained proof. Sir Humphry Rolleston, Mr. H. J. Waring, Sir W. Hale-White, and Dr. Henry Cotton of New Jersey responded to the toast, the last named expressing the indebtedness of American psychiatrists to their British colleagues. Dr. Percy Smith gave the toast of the Legislature, and the Earl of Onslow, in replying, referred at some length to the Mental Treatment Bill. He dated the new spirit in legislation and administration with regard to the insane to the quite recent transference of the Board of Control from the Home Office to the Ministry of Health. Lord Riddell, in acknowledging the toast, pictured a well organized municipality having, in addition to its seven existing inspectors, a mental inspector equipped with rather terrifying powers. Taking up a remark by a previous speaker, Lord Riddell expressed himself strongly against the ban upon professional advertising. He found it difficult as an ordinary man to take an impersonal interest in medical progress. Discoveries would always be associated in the public mind with persons, and Lord Riddell argued that when a medical man made a discovery it was quite good from the public point of view that it should be associated with his name. He did not see why it should be thought discreditable to doctors within certain limits of decorum, to indulge in indirect

it a source of comfort and encouragement as well. Parents can scarcely be expected to be anything but very sensitive when they find something wrong with a child on whom, perhaps, their hopes and ambitions were centred. Sometimes they will endeavour to stifle their fears; they may shut their eyes to obvious defects and find evidence of intelligence in the simplest biological reactions. It is, of course, much better that they should face the situation, though it is quite natural that they should be reluctant to do so. They may find that their fears are exaggerated, for, as Dr. Thomson points out, "some babies whose outlook to begin with seemed almost hopeless, improve far more than could have been expected, and do wonderfully well in the long run." In any case, as he repeatedly insists, the mother herself can do a great deal to bring about an improvement, and the earlier she begins the better. All mothers with defective children will find his book most useful; we can commend it also to social workers and medical practitioners because, though the advice is couched in simple language, it is given by a writer with a profound knowledge of children.

#### PROTECTION OF CHILDREN.

AMONGST bills with which Parliament is unlikely to be able to proceed during the present session is the "Children, Young Persons, etc.," Bill. It has been introduced by Mr. Ammon and a group of Labour members, and despite its barbarous title deserves more public attention than it has hitherto received. The bill is primarily a measure of consolidation, covering existing provisions for the protection of children and young persons, a section of the Statute Book urgently in need of revision. But the feature to which we would more particularly direct attention is the attempt to extend and strengthen existing enactments at certain points. Clauses 1 and 2, based on provisions in the Indian Penal Code, extend the law of homicide for the protection of a child which has partly issued from the mother's womb, and makes it a felony punishable by penal servitude up to ten years to cause the death of an unborn child—that is, a child no part of which has issued from the body of its mother—by an act amounting to criminal homicide if directed against a person. Part II would strengthen the provisions of Part I of the Children Act relating to infant life protection by requiring notice of reception of an infant apart from its parents to be given in all cases, although the period may be less than forty-eight hours, by bringing "relatives" in cases of illegitimacy within the provisions of the Act and by raising the age limit for special protection to 10. The Minister of Health is empowered to require local authorities to enforce the several provisions of the Act, and the right of the local authority to exempt particular premises from visitation is withdrawn. Powers and duties under this part of the bill are confined to County Councils and County Borough Councils, except within the administrative county of London. Section 12 of the Children Act, 1908, is revised, and the maximum penalties for cruelty to children and young persons are increased. The age of competence to marry is raised to 16 for both boys and girls.

#### DISSENSIONS AMONG ANTIVACCINATORS.

THE hotheads amongst the antivaccinators have once more been defeated, and the threatened disruption for the present averted. The *Vaccination Inquirer* of July 2nd contains a belated report of an animated scene at the annual meeting of the National Antivaccination League held in London on May 2nd. An over-zealous section of the members appears to be causing considerable anxiety to

the more sober-minded followers. The trouble arose through the reintroduction of the following resolution, which had been proposed but not adopted at the previous annual meeting: "That principle and policy alike demand that the National Antivaccination League should work for the entire prohibition of vaccination instead of the abolition of compulsory vaccination." The mover of the resolution made a fierce onslaught on the medical profession, describing doctors as "unmitigated scoundrels." Vaccination, he declared, was "organized blackmail." Two speakers, both laymen, protested against this onslaught on the medical profession. Several doctors were present and spoke, but the report contains no protest from them. Most of the speakers appear to have strenuously opposed the resolution, on the ground that it would "split the league," and that it was opposed to the liberty of the subject. Others threatened to leave the league, and others again urgently suggested that the resolution should be withdrawn. Eventually, however, a vote was taken and the resolution defeated. Thirty-seven voted against, seven in favour, and four or five persons present did not vote. The discussion reveals the real nature of the fight of the older stalwarts of the league. It has been with them for the most part a fight for people to please themselves whether they would submit their children to vaccination. In the present state of the law that liberty is conceded. Now that the chance of winning a crown of "martyrdom" has gone there seems much disappointment among a section of antivaccinators, and objection is taken to the conscience clause because it has removed the possibility of being sent to prison for refusal. It was remarked at the annual meeting that "the conscience clause has split up our society," and that the former organizing secretary went to prison "not because he was forced to go but because he knew that by doing so he would benefit the cause." Thus it came about that a resolution was submitted and carried by a majority of one (ten to nine): "That this meeting recommends all in a position to do so to refuse payment of that portion of the poor rate which is devoted to paying the expenses of vaccination, and pledges the full support of the league to all who do so." As an alternative to this recommendation, how would it be to suggest that the expenses of epidemics of small-pox should be paid by antivaccinators?

#### TO ENCOURAGE RURAL DOCTORS.

A SOLUTION to the difficulty of providing medical care for rural communities is suggested in the *Journal of the American Medical Association* (June 30th, 1923, p. 1930). The belief is expressed that any community that can support a medical practitioner can get one if its citizens are willing to pledge themselves to guarantee an income of 2,500 to 3,000 dollars (about £500 to £600 a year), and to interest the community in the support of the practitioner. This plan has worked out satisfactorily in a Middle West community, where the practitioner selected secured from his practice an income larger than the amount pledged, so that the guarantors were not called upon. The chief arguments advanced in favour of the plan are, first, that as the people of the community have a voice in the selection of their medical attendant, and as they have pledged themselves to his support, they will be disposed to consult him rather than practitioners in distant towns; and secondly, that young practitioners at the time they complete their medical training will be attracted to places where a reasonable income is guaranteed. In New Hampshire a law has just been passed which permits any town to appropriate sufficient money to support a resident medical practitioner when the town cannot otherwise obtain one.

has longer to clear up, and requires two to three weeks' treatment before much difference is seen. Cases of nasal polyps have improved greatly under the treatment, but different cases of otitis media and mastoiditis have not been able to produce an opinion; but mastoiditis certainly cannot be treated without operation.

**Tumours and Cysts of the Pancreas.**

ARMOUR (Arch. Med., de Chir., April, 1933, p. 112) publishes reports of three cases of tumours and cysts of the pancreas. A woman, aged 45, with a rare type of tumour of the pancreas (papillary) successfully removed and showing signs of recurrence. As is often the case in tumours of the pancreas, some cysts were in process of formation. (2) A man, aged 65, operated on for what proved to be a sarcoma of the pancreas; a peritoneum; except for trouble with pain and gastric stasis (which was eventually closed) the patient made good recovery. Both the tumours are rare in connection with the pancreas, and the author gives several photographs of the histological sections. The prognosis in peritoneal tumours is not good, but bad for perivascular sarcomata. For the most part it is impossible to diagnose these tumours, or at least their nature, before operation. The third case was a cyst of the pancreas. The author appends a bibliography of recent literature on the subject.

**Classification Disturbances of the Os Calcis.**

HEIM (Zentralbl. f. Chir., May 5th, 1933, p. 693) reports case of pain and swelling over the os calcis, associated with disturbance of the process of ossification of that bone—a condition which has already been described by several workers as Kohler's disease (epiphyseal bone of tarsus), a clinical entity, and is believed to be of the same pathogenesis. The case was that of a girl, aged 11 years, who had complained of pain in the left foot for three weeks, so that she could not stand upon the left foot. There was no history of trauma or other assignable cause. The left heel was swollen, especially at its outer part, and tender; the skin was stretched and pale, not reddened. In the radiograph the os calcis appeared indistinct and the trabeculae soft as though blotted out; near the epiphysis was an irregular clear space of about the size of a finger-nail. The epiphysis itself was indistinct in outline and irregularly ossified. The right os calcis appeared normal. The foot was kept at rest for four weeks in plaster, after which the heel had a normal appearance. At the end of seven weeks the foot was quite normal, and the patient experienced no pain whatever and had a normal gait. A radiograph taken after removal of the plaster showed no clear space in the os calcis, and the epiphysal structure was now regular; the bony trabeculae of the calcis still appeared somewhat poorly marked. The importance of recognizing the condition lies in the possibility of mistaking it for tuberculous disease. As in Kohler's disease, if the epiphysal bone, the prognosis is entirely favourable, and no operative measures are required. The pathogenesis is not yet explained, but there is no evidence that trauma, tuberculosis, syphilis, or rickets play any part therein.

**57. Pulmonary Abscess following Tonsillitis.**

E. J. CLARK (Boston Med. and Surg. Journ., May 31st, 1933, p. 846) reports a case of pulmonary abscess following tonsillitis, in which the tonsils were small and filled with cheesy debris, necessitating removal with forceps prior to the operation lasting over an hour. Since there is a real danger of such complication when a general anaesthetic is used, local anaesthetics is advisable unless contraindicated. The chief exciting cause being the aspiration of infective material into the lungs due to desensitization of the respiratory tract during general anaesthesia. The risk is increased among errors of technique which may act as causative factors, and infection of the accessory sinuses, etc. Amongst the factors are excessive manipulation, undue aspiration of the larynx, prolonged operation, and, in general anaesthesia, the failure to have the head lower than the body, and to guard against the aspiration of blood (a) during operation by the use of an efficient suction apparatus and (b) between the conclusion of the operation and the recovery of consciousness. The operation technique consists in the administration of the anaesthetic for four or five days, and one hour before operation is obtained by warm ether vapour given through nasal tubes; when the operation is completed the nose and throat are irrigated with hot saline solution, and the patient is placed in bed in Sims' position. By such careful attention to detail of technique the development of post-operative pulmonary abscess is reduced to a minimum.

**Obstetrics and Gynaecology.**

**58. Recognition of Fresh Effusion of Blood in the Abdomen after a Ruptured Ectopic Gestation.**

L. FISZACKER (Zentralbl. f. Gynäk., June 9th, 1933, p. 520) discusses on the great difficulty in the diagnosis of a fresh effusion of blood into the abdomen, especially when peritoneal irritation has caused meteorism, which obscures the diagnosis by peritonitis and paritonitis. The author states that the well known signs, such as a quick, turgid pulse, subnormal temperature, quickened respiration, etc., can all be obscured in other conditions. The history of amenorrhoea, however, usually, especially if the patient has a blood-stained vaginal discharge; but a tubal pregnancy may rupture without a period being missed, the rupture occurring before the next period was due—a condition of affairs which occurred in one of his cases. Features of the posterior fornix does not always yield blood in such cases. The blue-grey sublimation near the tubalities, which has been described by many authors, is commented upon, the symptom being most liable to be seen when associated with an umbilical hernia. Mention is also made of the sign, first noted by Doves, of pain in both shoulders, which can be quickly indicated by laying the patient's level on her back and applying pressure to the hypogastrium. This pain is supposed to be due to blood being forced between the liver and the diaphragm and causing irritation to branches of the phrenic nerve, which reflexly gives rise to pain in the shoulders. This sign has also been noted by Hehrle in several cases, and this same author puts forward a further sign—anaemia—which is corroborated by Fiszacker, who describes his case fully. The cause of the anaemia is supposed to be a depletion of blood supplied to the kidney owing to the great abdominal distension, and thus little or no urine is secreted. The author states that the sign is only of use if the secretion of urine has been normal before the tubal rupture.

**Menorrhagia of Puberty.**

ACCORDING TO E. PESTALOTTA (Revista d'Obstetricia e Ginecologia Pratica, May, 1931, p. 139), menorrhagia about the time of puberty is most commonly encountered in girls aged from 12 to 16; usually the patients belong to the middle classes and have just commenced college life. With expectant treatment and a fresh start the symptoms disappear within the course of a few months. In certain exceptional cases the menorrhagia is grave and progressive, and the resulting anaemia is resistant to all forms of treatment. In these patients physical examination is usually negative, occasional uterine hypoplasia, or abnormalities such as uterine bicornis, have been noted, and in one of the author's patients hysterectomy revealed very considerable bilateral ovarian hypertrophy. Irradiation of one ovary so as to produce a temporary partial castration has been recommended for intractable cases; and the spleen has been irradiated, apparently with success, in cases of menorrhagia associated with deficiency in the blood platelets. There is reason for assuming that grave cases of menorrhagia are underly dependent either (1) on a disturbance of the haemopoietic system in connection with the establishment of ovarian function, or (2), more rarely, when there are other associated haemopoietic disorders, such as epistaxis, purpura, etc., on a primary haemopoietic disorder.

**59. Pregnancy in Infected Myomatous Uterus.**

M. A. GROSS (La Gynecol., March, 1933, p. 164) records an unusual case of persistence of gestation in a uterus containing a submucous myoma. During the latter part of the eighth month the patient, a 24-year aged 26, suffered for six hours from severe pain accompanying violent uterine contractions. At the termination of labour, which occurred ten days later, a midwife had difficulty in extracting one leg after the other, the fetal parts had been delivered. Considerable abdominal pain continued to be felt, and four days after parturition there was fever, with marked cachexia. On the tenth day a tumour, recognized as a gangrenous myoma, protruded from the external os and was removed per vaginam. Subsequent interuterine exploration showed a perforation. The patient recovered after vaginal hysterectomy; the gangrene had extended to the fundus uteri in the neighbourhood of the insertion of the myoma, which was pediculated. A. BRYANT (when the operation is completed the nose and throat are irrigated with hot saline solution, and the patient is placed in bed in Sims' position. By such careful attention to detail of technique the development of post-operative pulmonary abscess is reduced to a minimum.

speaker's very pleasant privilege to extend the congratulations of the International Committee at once to Great Britain and to one of the greatest of British surgeons—to Great Britain, the generous nation, whose splendid soldiers spilled their blood on Flanders ground in defence of right and civilization; and to Sir William Macewen, the illustrious surgeon, whose name was universally known, and to whom he was glad to offer a tribute of admiration and respect. Speaking for the visitors, he said that they were very happy and proud to visit the British surgeons. During the war British surgery took a large part in the renovation of surgical methods, and gave several proofs of its well-known originality, and its careful and ingenious technique.

Dr. LEOPOLD MAYER (delegate from the Belgian Government), who spoke in French, referred to the recent visit of the Prince of Wales to Belgium. His Royal Highness, in honouring the Society with his presence, had doubtless wished to show that he had not forgotten it was in Brussels twenty years ago that the Society was founded, and that its standing committee was composed of Belgians. He also, in thanking the Ministers who had welcomed the gathering, referred to the cordial relationship which existed between Great Britain and Belgium. Since the last congress there had been heavy losses in their ranks by death; he referred particularly to the death of Sir Charles Ryall, who had helped to lay down the lines on which the present meeting was to be held. He thanked Mr. Roberts and Sir D'Arcy Power for the amount of work and thought they had put into the arrangements for the gathering. He mentioned that at a meeting of the International Committee held the previous afternoon 184 new members were admitted to the Society, bringing the total up to 748, representative of twenty-eight nations. Certain alterations in the statutes would be submitted in order to prevent the financial position of the Society being seriously compromised by the disorganization of the exchanges. Contrary to the usual custom, the scientific sessions at the present meeting would take place in the mornings, leaving the afternoons to be devoted to visiting hospitals, laboratories, and university institutions, but this would not mean that the scientific sessions would be shortened or ill-attended. In conclusion he welcomed certain representatives in particular—those, namely, from Jugo-Slavia and Czecho-Slovakia, from Russia, and from Latin America—and paid a tribute to the Presidents of the sixth and the fifth congresses Sir William Macewen, whose qualities were very eminent, and Professor Keen of Philadelphia, whose activity and alertness seemed to belie the fact that on the previous day he had entered upon his eighty-seventh year.

Sir WILLIAM MACEWEN then delivered his presidential address, the Prince remaining until its conclusion. The address was received with much acclamation. It is published in full at page 91.

## DISCUSSIONS.

### SURGERY OF THE ENDOCRINE GLANDS.

The first meeting of the International Congress of Surgeons dealt with the surgery of the endocrine glands and from this debate the thyroid was excluded. A large field was thus given to the reporters, a field perhaps too vast for adequate discussion.

Dr. VEAU, of Paris, first spoke on the surgery of the thymus in early infancy. Three types of surgical intervention had been practised in hypertrophy of the thymus. Rehn, Koenig, and Deneke, had contented themselves with fixing the organ in the substernal space. Results had not been satisfactory, perhaps because respiratory movements were too great. The next type of operation was a resection of the manubrium sterni with or without thymectomy. It was important to consider the question of the removal of the gland in these cases. Dr. Veau did not think that resection of the bone without thymectomy was justified. It had never been proved that the trouble caused by a hypertrophied thymus was due only to an antero-posterior compression. Removal of the manubrium after thymectomy should be reserved for those cases in which it had been impossible totally to resect the superior pole of the adherent gland. Subcapsular thymectomy—an easy and not

a dangerous procedure—should be the only routine operation in cases of enlarged thymus. The results of the operation were excellent. In spite of the desperate condition of many of the patients he could never remember a case of immediate post-operative mortality. Thirty per cent. of the infants were dead a month after the operation. This mortality must be carefully considered; deaths were due to several causes. In babies who had been submitted to a previous tracheotomy there was a great danger of infection of the wound. In cases of dyspnoea of unknown cause a blind tracheotomy should never be done. "If it is necessary to operate, do a thorough operation and see what you find." Bronchopneumonia was another cause of death. Care must be taken not to operate wrongly on children with tuberculous glands. If this were done generalized tuberculosis followed. Again, infantile diarrhoea sometimes caused a fatal issue. There were three main symptoms of an enlarged thymus—permanent dyspnoea, crises of suffocation, and stridor. In two-thirds of cases the dyspnoea was immediately cured by operation; in four-fifths the suffocation disappeared; the stridor was less amenable to treatment. It was a habit and only gradually disappeared. Ablation of the thymus did not interfere with growth. Nor should it, for only the superior poles of the gland were removed. The operation was a good and simple one. However, another therapeutic agent was at hand. X-ray treatment cured these babies without operation; the rays could be applied blindly—they seemed to do no harm. If a doctor was even suspicious of a hypertrophied thymus, his duty was to send the patient to a radiologist. Then the diagnosis was less important. A thymectomy ought not to be done like an exploratory laparotomy. One or two points in connexion with radiotherapy should be noted. Occasionally it was ineffectual. If after one or two applications the symptoms persisted, thymectomy should be done. It was said that grave events sometimes followed the application of the rays. After six, seven or eight hours symptoms suggesting infantile cholera developed. The child became cold, a little dyspnoeic, and sometimes had had diarrhoea. The periphery was cold; there was a high central temperature. *Post mortem* one found the gland had disappeared. Sometimes there were symptoms of a mild meningitis. These cases were so rare that they should not prevent x-ray treatment; but till the effects of the rays were proved by time the surgeon must not imagine his work on the thymus finally completed. There was, moreover, for him always the urgent case of the child near asphyxiation in whom the cervical incision had displayed a hypertrophied thymus.

Although Dr. LORRMOIR of Brussels did not speak next, it will be of interest to take his remarks at this point. The physiology of the thymus was, he said, still largely a matter of conjecture. Probably it was related in some way to growth. The indications for operation he believed to be many. Thymic asthma—too well known to need description—respiratory insufficiency, atresy, general debility, all called for thymectomy. There was an analogy between ablation of the thymus and of adenoid vegetations. The time would come when thymectomy would be practiced as frequently as the removal of adenoids is now accomplished. The operation was simple. Any anaesthetic could be used—he usually advocated chloroform. Considerable care must be taken in advising the drug. The local anaesthetic was impossible in a baby. The submembranous enucleation of the gland was the most difficult part of the operation, which could be total or subtotal. There should be practically no bleeding. He believed that the x rays affected other structures besides the thymus and were thus dangerous. They should remember that the operative mortality was nought.

Dr. W. J. MAYO, of Rochester, U.S.A., discussed the splenic syndrome. From the time when the Greeks were supposed to have removed the spleen from their long-distance runners there had not been, till recently, any great advance of knowledge in its functions. It was now known that the spleen was concerned with the blood and was closely associated with the liver. It was chiefly a mechanical filter removing from the blood degenerated red cells and toxic agents above colloid size. Such were micro-organisms and debris on which it acted before sending them to the liver for further detoxication and elaboration. It also

LONDON HOSPITAL

## CATGUT

"Ultran" Catgut is prepared under the strictest aseptic conditions in the special laboratories which have been set up for the purpose at the London Hospital, and is in use in the 15 operating theatres there.

The unique feature is that sterilisation commences immediately after the splitting of the intestine before the gut is twisted. This ensures that no contaminating debris (which almost invariably would escape sterilisation), is enclosed within the turns, later to become the focus of infection at the site of operation.

The sterilisation of every batch is verified by bacteriological control, both aerobic and anaerobic tests being carried out. The time factor for absorption is practically constant and can be guaranteed in every grade.

The tensile strength is such that even in the finest gut there is a wide margin of safety. Every batch of London Hospital Catgut is tested by this specially designed machine which accurately registers the breaking strain. No catgut is sent out which does not pass the minimum test of the standard, which is considerably higher than that usually accepted for surgical catgut. London Hospital Catgut is, however, generally found to be much above the minimum test standard.

The fact that "Ultran" Catgut is made at the London Hospital and is continuously in use there, ensures a constant standard of excellence which cannot be assured with any other ligature or suture.

Descriptive booklet will be sent post free upon application to the sole distributors—

LONDON HOSPITAL  
EYELESS NEEDLE

The New

avoids the possibility of catching or laceration owing to the sharp point of the needle. These aseptic needles—straight, curved, round of cutting—are supplied complete with sterile swabs, packed in glass tubes ready for immediate surgical use.

3. Operative accident.
4. Post-operative pituitary toxæmia.
5. Post-operative pneumonia.
6. In trans-sphenoidal operations septic infection.

Mr. Sargent advocated the frontal approach to the gland.

Dr. SERGE VORONOFF said that in the Collège de France he had been able to obtain durable ovarian, thyroid, and testicular grafts. Recently he had become interested in testicular grafting in men. Owing to the difficulties of obtaining human graft material he had utilized the testicles of chimpanzees and cynocephalic monkeys. Since 1917 he had been seeking a method to ensure long survival of the grafts. Many experiments on animals had been made. At present he had three cases dating back two years and nine months; two cases dating back two years and seven months; and one case dating back two years and eight months from operation. In all these cases the effects of testicular hormone artificially obtained by grafting was very apparent. Not only was there a subjective appreciation by patients, but such physiological phenomena as lowered blood pressure, loss of weight in obese subjects, production of better vision in hypermetropic subjects through increased tonicity of the lens and accommodative muscles, new growth of hair, etc., had been demonstrated. The size of the gland, or piece of gland, transplanted was important. Early he found that an entire testicle would not grow. Then he went to the other extreme and put in minute pieces. These were absorbed. Now he divided a testicle into six pieces and grafted three of the lamellae on to the visceral surface of one tunica vaginalis, and three on to the other. These were successful. All aseptic precautions were taken. Testicular grafts from young monkeys had not been successful; the animal must be mature. Forty-four of these cases had been done; of these six were doctors. The effects had been put down to auto-suggestion. For three months after the operation there were no appreciable effects. During these three months the doctor patients scoffed. Afterwards they began to appreciate the effects of the treatment.

Mr. IVOR BACK, who has been working in Paris, supported (in English) Dr. Voronoff's contentions. Mr. WALLON advocated the frontal approach to the pituitary gland. Dr. BANTINE remarked that insulin helped surgery by getting rid of acidosis and acetone and thereby permitting grave operations on diabetics.

Drs. HENRY (Dublin), KOCHER (Berne), FROELL (Stockholm), Mr. PYBUS (Newcastle-on-Tyne), and others spoke.

[The remainder of the discussions will be reported in our next issue.]

#### CONVERSAZIONE AT THE UNIVERSITY OF LONDON.

On the evening of Monday, July 16th, a reception conversation in honour of the Society was held at the University of London. The guests were received in the marble hall by Mr. H. J. Waring, Vice-Chancellor of the University, and Mrs. Waring. The String Band of the Scots Guards played a selection of music in the grand hall, and the galleries of the Imperial Institute were also open. In the library of the university were displayed a number of rare books, including the contemporary manuscript of the life of the Black Prince, which has been placed on permanent loan by the Prince of Wales. The guests, who numbered over six hundred, included, in addition to members of the International Society of Surgery, many representatives of universities and other learned bodies.

#### PRESIDENT'S RECEPTION.

On July 17th at 8.30 p.m. the President of the Congress, Sir William Macewen, received members of the Congress in the rooms of the Royal Society of Medicine. During the evening the President gave a further discourse, illustrated by lantern slides, on the growth of bone.

#### LUNCHEON BY THE GOVERNMENT.

The British Government on July 18th entertained at luncheon at the Savoy Hotel a number of members of the Congress, and some others. The Minister of Health was in

the chair, and had on his right hand Dr. Willems (Liège), chairman of the permanent Executive Committee of the congress, and on his left Dr. Henri Hartmann, professor of surgery in Paris. After giving the toasts of the King, and of the Sovereigns of the Kingdom and Presidents of the Republics represented, Mr. Neville Chamberlain gave that of "Our Guests" in a short speech in which he referred to the presence of Dr. W. W. Keen of Philadelphia, who was president of the last congress of the International Society of Surgery in Paris three years ago. He touched on what has been accomplished in this country for the health of the people, as evidenced by the decline in the death rate and in the rate of infant mortality, and expressed the pleasure with which the British Government welcomed the representatives of the profession, which in all countries was labouring for the same end. He coupled the toast with the name of Professor Hartmann, who in a brief reply referred to his earliest visit to this country to learn the system of antiseptic surgery introduced by Lister and demonstrated by him at King's College Hospital. The president, Sir William Macewen, proposed in a few words the health of Mr. Neville Chamberlain, who made a brief response.

#### NEXT MEETING.

It has been arranged that the next congress of the Society shall be held in Poland, at Warsaw, in 1926.

#### BADGE.

The badge of the congress is a bronze medal having in relief the seated figure of John Arderne, which was reproduced in our columns on December 9th, 1922 (p. 1127), surrounded by the inscription "Int. Surg. Soc. VI. Congress: London, 1923."

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

#### Small-pox.

SIR GEORGE BERRY inquired, on July 11th, whether the Minister of Health was satisfied with the manner in which the Vaccination Acts were being administered, and whether, if not, he was prepared to take steps to enforce rigid compliance with them. Mr. Chamberlain said that the responsibility for the administration of the Vaccination Acts rested with the boards of guardians and their vaccination officers. He was not satisfied that the Acts were being properly administered in all districts, and he was considering what steps could be taken to secure improvement in this respect. Dr. Fremantle asked whether the Minister would consider the transference of the administration of vaccination to the general sanitary administration under the sanitary authorities. Mr. Chamberlain replied that this question had been under consideration, but he could not undertake to introduce the necessary legislation during the present session.

The following statistics have been supplied by the Ministry of Health:

No. of Cases of Small-pox Notified in each of the Years 1892-1910 inclusive in certain Large Towns (including London), with a Total Population of such Towns.

| Year. | Cases. | Population. | Year. | Cases. | Population. |
|-------|--------|-------------|-------|--------|-------------|
| 1892  | 1,9    | 11,833,279  | 1902  | 13,923 | 13,697,791  |
| 1893  | 10,438 | 11,894,930  | 1903  | 7,383  | 13,781,337  |
| 1894  | 6,319  | 12,312,200  | 1904  | 5,766  | 19,645,072  |
| 1895  | 1,942  | 12,257,700  | 1905  | 2,333  | 20,333,553  |
| 1896  | 2,713  | 12,769,163  | 1906  | 1,020  | 20,653,699  |

The figures for 1922 are not yet available.

## British Medical Association.

NINETY-FIRST ANNUAL MEETING, PORTSMOUTH, 1923.

President's Address

BY

## ENVIRONMENT AND HEALTH.

CHARLES F. CHILDE, B.A., F.R.C.S., M.R.C.P.E.,

SENIOR SURGEON, ROYAL PORTSMOUTH HOSPITAL.

AND

BY

tax of 1s. 6d. in the £.

Portsmouth has been singularly fortunate in the honour you have bestowed upon it in visiting it twice within a quarter of a century. Considering that it does not possess a university and is not a centre of medical education—a handicap of no small extent in a gathering of this character—it is a great compliment that, having met here so recently as in 1909, the Association has repeated its visit this year.

It will recall two honoured memories if I mention that the late Dr. Ward Cousins was your President in 1909, and the late Alderman Sir Scott Foster our Mayor. The former was for years a member of the Council of the Association, a very regular attendant at these meetings, and he was one of the staunchest and most active supporters of the British Medical Association throughout a long life; that the latter was one of the most distinguished and respected public men that Portsmouth has known. It is peculiarly fitting that his younger brother, equally distinguished and equally respected in his public life, should occupy the mayoral chair to-day on the occasion of your second visit. Inasmuch as the Printing and Publishing Committee has compiled a *Book of Portsmouth*, which will be presented to every member on registration, I do not propose to say anything of the history of Portsmouth, though it would have furnished engrossing material for an address, and I was sorely tempted to avail myself of the opportunity. But on consideration it seemed hardly fair to ask the Committee to go to the trouble of getting out a *Book of Portsmouth*, and then to anticipate the result of their labours by my remarks to-night. I have therefore chosen quite another subject. But before embarking on it, I should like to touch in the briefest way upon two or three current local topics. It was not till 1920—that is, three years ago—that Portsmouth, for the first time in its history, forsook its island home in Portsea, and crept out on to the mainland, embracing the villages of Cosham immediately to the north, and to the west some 500 acres of the southern slope of Portdown Hill. This extension, there is not the slightest doubt, will be in the future—indeed it has already begun to be—an invaluable asset to the town; for here is one of the most salubrious building sites in the kingdom, and within easy distance of the island of Portsea. It is

that embodied in the first words I have to say to you. They are to extend to you, as President of this Association, I do this first in the name of the Portsmouth Division, which has invited you to hold your meeting here, and is consequently your official host, yet I wish at once to assure you that this welcome is equally shared by the General body of medical practitioners in the neighbourhood, by the Corporation, by the navy, military, and air forces, by the business community, by the press, and by all classes of the inhabitants. All have contributed without stint in their endeavour to make this meeting one agreeable to you, as well as worthy of the hospitality and prestige of Portsmouth; and I feel, and I am sure the Division would feel, that I had been guilty of an omission if I did not freely and generously acknowledge this at the very outset. This whole-hearted joining of hands for a common purpose is evidence of a loyal and healthy citizenship, of which Portsmouth has furnished abundant examples in the past, both in the grim circumstance of war as well as in many historical functions of peace.

We shall have amongst us during the present week men and women belonging to the profession of medicine from all over the globe; from all parts of the British Isles; from our overseas Dominions; from the great continent of America. These are our own flesh and blood; all members of the Anglo-Saxon community of peoples. Need I say they are all equally welcome? And need I say that equally welcome with these are our distinguished foreign visitors? Indeed the word "foreign" is somewhat out of place at our meetings; for there are no foreigners in the profession of medicine. Medicine knows no frontiers. It is a world-national conception of society. We have in being a Medical League of Nations. As far as the policies of medicine are concerned, as far as its aims and ideals are concerned, as far as its aims and ideals are concerned, there is only one race, and that the Human race; only one nation, the nation of Men and Women. All its discoveries, all its developments, all its weapons, both offensive and defensive, are common property, to be used by all, for the benefit of all. It has no crafty policies, no patents, no jealously guarded secrets, no selfish practices, at the disposal of one nation to the detriment of another, or of one class to the detriment of another. Its enemies, disease and death, are foes common to all mankind. If the nations of the world devoted their energies and opportunities internationally in the same sense that medicine does—to fighting the universal foes of mankind that confront us at every

## England and Wales.

### MENTAL HOSPITALS ASSOCIATION.

THE fifth annual meeting of the Mental Hospitals Association was held at the Guildhall, London, on July 12th, under the chairmanship of Alderman Francis Bato.

The chairman said that the chief matter of discussion was the Mental Treatment Bill, which included many of the proposals which the Association had actively pursued in the past. It was the view of the Executive Committee of the Association, which had addressed a communication to the Minister of Health on the subject, that the bill contained provisions which, if passed into law, could not fail to prove beneficial to those suffering from incipient mental illness, although the various clauses were not as far-reaching as had been desired.

Various suggestions on the clauses of the bill as put forward by the Executive Committee were then considered. The principal discussion centred around Clause 4, Subsection 4, which states that one of the medical practitioners making a recommendation for treatment shall be a person approved for the purpose either by the Board of Control or by the local authority. The Executive while realizing that a similar provision existed in the Mental Deficiency Act, 1913, was of opinion that in this case it was open to grave objection. In small areas it would impose on either the Board or the local authority the obligation of making invidious distinctions between local medical practitioners. No useful purpose would be served by the enactment, and it was highly probable that it would add to the expense and inconvenience which must necessarily attach to any application made on behalf of a person requiring temporary treatment. An amendment was moved by Alderman H. E. Witard (Norwich), seconded by Alderman D. J. Davis (West Ham), to the effect that the practitioner in question should be one who had expert knowledge in mental cases. It was urged that the stigma attaching to any who had spent even a short time in a mental institution was such as to make it imperative that the responsibility of sending anyone there should rest only on the expert. On the other hand, it was urged that there were not enough practitioners having expert knowledge available, although every medical practitioner had a general knowledge of the subject. The amendment received little support, and was negatived, and the Committee's recommendation objecting to the subsection was endorsed. Another suggestion which was agreed to by the meeting was that certain provisions with regard to after-care militated against the voluntary principle. It was considered that it was undesirable that after a patient had been discharged upon a trial he should be in any way associated with the institution.

The hope was also expressed by the meeting that the scope of the subsection dealing with out-patients might be amended, and the privileges enlarged. It was pointed out that if the definition of the word "institution" in the Lunacy Act, 1890, and in the Mental Deficiency Act, 1913, was to be applied to the bill, a visiting committee would not be able to contribute to the cost of an out-patient department for mental treatment in a general hospital. Moreover, where, as in many instances, the mental hospital was situated at a considerable distance from large centres of population, it might be desirable to institute an out-patient department away from the mental hospital. Other suggestions, introduced by the Committee and upheld by the meeting, concerned the question of expense of administration and maintenance. Another question which was brought forward was the responsibility of the Ministry of Pensions for the cost of ex-service men in mental hospitals. A matter which had arisen in this connexion in Newcastle, where it was alleged the Ministry had refused to accept the cost, was referred to the Executive Committee.

A long report was presented on the proceedings of the Joint Conciliation Committee which has been engaged on the work of improving and stabilizing the conditions of service of the nursing staff in mental hospitals. The report was adopted.

Alderman Bate was reappointed Chairman of the Association, and all the officers were re-elected.

### NATIONAL COUNCIL FOR MENTAL HYGIENE.

A public meeting called by the National Council of Mental Hygiene was held at Caxton Hall, Westminster, on July 12th. Sir Courtauld Thomson, who was in the chair, said that this was the first meeting of the National Council of Mental Hygiene since it became a legally constituted body. Its main object was the preservation and improvement of the mental health of the nation. This vital question was being studied, and would be studied more in the future, by various schools of thought. The fact that every avenue leading up to the solution of this difficult problem was now being explored was not a sign of weakness, but rather showed that the movement was alive and virile. It would be the duty of the Council to co-operate with every association and public body which was honestly trying to throw light on this important question. Laymen like himself on the Council considered it a great honour to be associated with the medical profession in this work. There were many ways in which laymen could help: they could stimulate and support legislation, advise local authorities, assist in propaganda campaigns, and relieve their medical friends of some of the routine and organization work necessary to a movement of this kind.

Mr. Clifford Beers, founder of the National Committee for Mental Hygiene in the United States, then gave some account of what is now being done in this direction there. A beginning had been made in those preventive directions which were likely to yield the best results. About 90,000 dollars a year was given to the National Committee for Mental Hygiene to assist in preventing juvenile delinquency. The Committee had established three mobile clinics each of which was given to a particular city for a year in order to demonstrate what could be done with the "problem" child of the city, and as a result permanent clinics had now been set up at St. Louis, at Norfolk (Virginia), and at Dallas (Texas). An international congress was to be held in the United States in 1925, and he believed that within ten years the mental hygiene movement would be the outstanding health movement of America. He spoke at some length on suicide cases, two-thirds of which, he believed, might be prevented. The number of suicides in the United States was between 10,000 and 15,000 a year, and this toll of life would continue until mental clinics were in general operation.

Sir Maurice Craig said that until now very little had been done in mental cases before a complete breakdown occurred. Yet mental disorder was not a sudden event; it was of slow growth, and long before disintegration took place there were minor mental changes and emotional disturbances. The beginning of mental trouble was often an unhappy childhood. As for the child who developed criminal tendencies, he had asked an authority on the subject how early he could tell the criminal type in school, and the reply had been that this could be done very frequently at as early an age as six or seven. Asked further what was done in these cases, the reply of the authority was "next to nothing." The work of the Council, Sir Maurice Craig continued, was to collect knowledge, to survey the position, to instruct the public, and to join hands with similar bodies in other countries, for this movement was becoming international. It was most important that medical men and laymen should work together; they could not get behind the medical problem unless this were done.

Viscount Burnham said that one of his vivid recollections was of seeing in the City of Damascus thirty years ago people who were supposed to be suffering from mental affliction chained up against the bare wall of a brick enclosure. That was an oriental example of extreme barbarity, but in its principle and essence, apart from its more obvious cruelty, it was not so very far removed from the manner in which mental disorder used to be treated here and in nearly all countries.

A hearty vote of thanks was accorded to the Chairman and speakers on the proposition of Dr. Helen Boyle. The meeting was attended by a number of distinguished people, including the Spanish Ambassador.

ing conditions which favour the growth, dissemination, and virulence of the infecting organism, by so altering environment and increasing natural resistance, whatever that may presently mean, that many diseases which have been very prevalent and very fatal in the past have almost or entirely ceased to exist, and are no longer of any account. Let me give you one or two very familiar examples.

"Take typhus fever. During the last century it prevailed in all the large cities of Great Britain and the Continent. So late as 1875 in England and Wales there were 1,199 deaths from the disease. During recent years the name "typhus" has seldom appeared in the Registrar-General's returns. It is a disease essentially dependent on filth and overcrowding. Bad as these conditions are even now in our large industrial centres, the disappearance of this disease is evidence of an improvement as compared with half a century ago—an improvement in environment and living conditions, sufficient to have caused its disappearance altogether. After the peace of 1815, following a long and exhausting war, when the economic position was somewhat similar to that existing at the present time, typhus fever and relapsing fever, which occurs under similar conditions to typhus, were rife in England and Ireland. No such catastrophe has accompanied the economic depression following the last great war.

"Take, again, typhoid fever. It is a water-borne disease. Bad drains and a contaminated water supply are the factors favouring its distribution. Its prevalence or the reverse in a community is the measure of their sanitary intelligence and enterprise. Filth, overcrowding, and bad ventilation are factors conducing to its prevalence, by lowering natural resistance. The marked decline in typhoid fever is again the result of an improvement in environment. Typhoid fever has declined from 375 per million in 1870 to 25 per million at the present time. In Portsmouth typhoid fever, quite prevalent in the town when I came here thirty years ago, has almost ceased to exist.

"These are examples of diseases which have disappeared, or are disappearing, owing to action following an intelligent and comprehensive of the conditions and environment favouring their distribution. "Now, "environment" is obviously a very wide term. It embraces living conditions generally. The amount and quality of food and water, the presence or absence of domestic hygiene, the supply or not of good drainage, the furnishing or not of healthy conditions in factory and workshop, the prevalence or not of smoke and fog, the provision or not of adequate open spaces, playgrounds, and recreation grounds, access or not to sound education—these and many others are all factors in environment. And it is satisfactory to note that these matters are receiving from governments and local authorities some of the attention which all of them deserve. But I propose to-night to consider for a few moments the special environmental factors governing the slum areas of our great industrial centres—the lack of fresh air and sunlight, and the cramped and penalizing conditions to health, both moral and physical, owing to overcrowding; and to inquire what bearing these factors have upon four out of five of the most formidable endemic scourges which afflict all northern civilized peoples to-day.

"The five scourges I allude to are Cancer, Tuberculosis, Rickets, Venereal Disease, and Alcoholism. Tuberculosis and rickets account for most of the cripples we see about us; cancer, tuberculosis, venereal disease and alcoholism account for most of the deaths; venereal disease and alcoholism account for most of the misery and moral degradation of our race. "We may dismiss cancer at once from the count. The humiliating confession must be made that we know very little about it. That it has some relation to civilized environment seems evident from the fact that it is a comparatively rare disease among primitive races, and that it is certainly making rapid headway among all civilized peoples. But of the nature of the environment favouring its activities we are in complete ignorance. It is neither

food air nor fresh air, neither hardship nor indulgence, neither poverty nor riches. Cancer like death—

"Aequo pulsat pede pauperum tabernas,

Regnumque turres,"

"The only thing we know about it which are worth knowing are its age incidence, its relation to chronic irritation, and the fact that it is in its beginnings a local disease, and that therefore it can be cured by early removal in those situations where removal is possible. "This is practically all we know about cancer. I wish to make only two comments. The first is that this knowledge is not enough. In an age which has yielded the secrets of so many diseases it is a point of honour with the medical profession not to rest content till this pressing problem has been solved. With the public it is not only an obligation but, from the point of view of their own interest and safety, a vital necessity to furnish the financial means and solution, and to see to it that research is not crippled or stunted by any niggardly parsimony. "The second comment I make is this: The most important fact we know about the disease is that in its beginning it is local, and that its course is a centrifugal spread from its local point of origin. Is that knowledge anything like as productive as it might be? Undoubtedly it is not. Notwithstanding the fact that cancer has been cured over and over again by modern operation—a fact which in itself proves that it is curable—yet I believe patients come no earlier to the doctor with it than they did thirty years ago, though time is the very condition of the only cure we possess for it. Many medical men, and I confess I am one of them, are of opinion that there is considerable room for improvement in this direction. Without resort to any sensationalism some obvious steps could be taken to spread the knowledge of a few very simple facts about cancer. This would give a by no means unwarranted ray of hope to the public and would enable some of the victims of this terrible disease to apply in time to have, at all events, a chance of cure or freedom from recurrence, whichever you like to call it. This by the way.

"I pass on to the consideration of the other four scourges—tuberculosis, rickets, venereal disease, and alcoholism. Tuberculosis is first. We know the cause; it is the tubercle bacillus. We know also the prime and essential conditions of its cure; they are fresh air and sunlight. These are not only the essential conditions of its cure, but are almost the sole conditions. Those of you who are interested in the subject will have an opportunity of visiting the establishments at Alton and Hayling Island, under the able administration of Sir Henry Cavendish, where the cures are fresh air and sunlight. Dr. Koller of Leyden read a most instructive paper at the Glasgow meeting last year, and quoted many instances of cures, and lasting cures, by these agencies in all regions of the body. It is foreign to my purpose to discuss to-night the method or supposed method of their action, or the method of their application. If, then, whether by directly controlling the activities and virulence of the tubercle bacillus itself or by fortifying the natural resistance and so enabling the human organism to establish an immunity to it (it matters not, the result is the same)—we are not justified in the converse conclusion, that the spreading ground of this disease, the environment most encouraging to its activities, are the sunless, airless, overcrowded, and insanitary slum areas of our great cities, where houses are built forty or more to the acre, and stand back to back, and side to side, like any jigsaw puzzle, so that fresh air and sunlight, the proved destructive agents of the tubercle bacillus, can never enter? Is it a sound economic proposition to equip and maintain, at the cost of millions of the taxpayers' money, sanatoriums for the so-called cure of tuberculosis, while we guard intact the very preserves of this disease by the exclusion of fresh air and sunlight, which cost nothing, and maintain in our midst a soil which can breed more tuberculosis in a week than all our sanatoriums can cure in a year? Dr. Koller says: "Having played an immense part in the genesis of child and adult tuberculosis: the community bears the responsibility of the waste of human lives through insanitary houses."

0.34, by 5.30 p.m. it is 0.48. Yet all his symptoms have disappeared and he is full of the joy of life—no thirst, no polyuria, no neuritis.

This case is typical. What has struck me most is the quick acquisition of a sense of mental and physical well-being. Of course in all these cases I correlate the dose of insulin and the diet with the blood sugar findings as well as one can with the limited amount of insulin available.

In view of these results one can only conclude that insulin is a practical proposition, and that every diabetic patient who is handicapped in the struggle for existence by the complaint should be urged to spend what money he can afford on insulin, resting assured that it shall be returned to him a hundredfold in strength, happiness, and increased earning capacity.—I am, etc.,

Hornsea, E. Yorks, July 11th.

ALEX. J. W. CALDER.

### HISTORY OF MILITARY MEDICINE.

SIR,—In the BRITISH MEDICAL JOURNAL of March 10th (p. 419) General Sir W. G. Macpherson prints a long and courteous review of my *Notes on the History of Military Medicine*, in which, while pointing out several inexcusable blunders, he indulges in a little quibbling at my expense. At the end, where his chaffing culminates in "pyramidal pleasantries," my reviewer intimates that I do not even know the military significance of barrage fire or that daylight salvage of the wounded was possible before the barrage was invented. If one considers, however, the sad plight of wounded soldiers left for hours on the field in many great battles of the past (including some of the world war), I think it will be admitted that the barrage promoted efficiency in evacuation of the wounded, apart from its purely military aim.

My statements about the ultimate use of the evacuation hospitals and centres of triage referred, of course, to the American lines. In regard to the British casualty clearing stations, the parent of these devices, I stated on page 192 that they were invented in 1907—that is, five years after the conclusion of the South African war. That I date their origin in the period of the war itself seems an unwarranted inference.

My figures concerning Marlborough's march to Blenheim were not the result of mathematical calculation, but were taken on trust from Sir A. A. Gore's *Story of Our Service under the Crown* (1879). I regret that a book so interesting and informing should be misleading on this point. My figures of national battle losses in the world war are, for the most part, obviously rough estimates, but were the only thing of the kind available. They may be appraised in the light of Dr. Johnson's dictum: "Round numbers are always false." Those who expect too much from statistics of wars with heavy battle losses, particularly those in Eastern Europe from the earliest periods, may find consolation in the French proverb, *La plus jolie fille au monde ne peut donner que ce qu'elle a*. How such round numbers were ever evolved from the confusion and disorder following a pitched battle is one of those *problemas para solucionar* of which the Spanish-speaking physicians incessantly write. This is true of some of the statistics of the Napoleonic, Crimean, and Austro-Prussian wars. My failure to account for the work of the Austrian medical department in the pre-Napoleonic period is a serious error of omission, but that Brambilla and Sax are more important than Larrey and Letterman in the history of "collection, evacuation, and distribution of the wounded" will be news to American medical officers. I saw no mention of this view in the English, German, and French sources available (including Longmore). As for the assertion that the Brambilla-Sax system was subsequently adopted by the Continental and British armies, I am at this moment 10,000 miles away from any reference books, and beg that this momentous claim to perhaps the most important advance in modern military medicine be confirmed by textual verification.

The statement that my *Notes* were "largely culled from the writings of Frölich" will not, I think, be confirmed by anyone who is familiar with these writings or who has examined the pamphlet and its footnotes in relation thereto. Frölich's derivation of the Homeric *ἵππος* from the concept "arrow" rather than from the verb "to heal," has, how-

ever, some justification, in that the Homeric "healer" was not a medicine-man but a wound-healer, as in the old High German epics in which surgery is *Heilkunst*. In this view, the verb *ἰάομαι* would connote wound-healing, and might have the same root-concept as *ἵος*.

In conclusion, I beg to say that my pamphlet was intended, not for the "instruction" of medical officers proper, but as a stimulus to further study among student officers at the Army Medical School, Washington, D.C., and that its title "*Notes*" conveys this fairly modest intention. I am glad to have perpetrated a few blunders in 206 pages, in view of their eventual correction by military authority so high.—I am, etc.,

F. H. GARRISON,  
Lieut.-Colonel, Medical Corps, U.S.A.

Manila, P.I., May 17th.

SIR,—You have kindly given me an opportunity of replying to Lieut.-Colonel Garrison's letter in which he criticizes my review, in the BRITISH MEDICAL JOURNAL of March 10th, 1923, on his *Notes on the History of Military Medicine*.

I will be as brief as possible. But first of all I must disclaim any attempt at quibbling or pleasantries in that review, and, moreover, I venture to think that no unbiased reader of it could discover any indication of such in it. I certainly fail to do so myself, and, in fact, nothing could be further from my wishes or intention than to indulge in any frivolity at the expense of so distinguished a colleague as Colonel Garrison, for whom I have the greatest respect and admiration, and from whom I have learnt so much. It was a reviewer's duty, however, to point out the errors which Colonel Garrison himself handsomely acknowledges to have occurred in his *Notes*, more especially as historical errors are apt to be perpetuated by repetition.

As regards barrage fire, I can state definitely, from personal observations during almost all the battles on the British Western Front, that wounded were cleared as rapidly before as after the introduction of barrage methods of attack; barrage, in fact, had absolutely no influence one way or the other on the work of clearing the wounded.

Colonel Garrison has entirely misread my remark about the casualty clearing stations. I did not say that he dated their origin to the South African war. What I did say was that he is wrong in implying their origin to the faulty organization of the field medical units during that war instead of to their faulty organization after the war—that is to say, to the faulty organization of the field ambulances during the reorganization of the bearer companies and field hospitals which existed at the time of the war.

He has cleared up the statement about Marlborough's march to Blenheim, but in doing so he offers us an extremely interesting example of how historical truth becomes perverted. He now tells us that the authority for his statement "Marlborough's celebrated march to the battlefield of Blenheim covering 1,176 miles in 86 days" was Sir A. A. Gore's *Story of Our Service under the Crown*. This book was a reprint from an article by Surgeon-Major A. A. Gore in *Colburn's United Service Magazine*, and this is the statement in it:

"Marlborough's campaigns are also to be remembered for two marches of historical interest. His celebrated march commencing 19th May, 1704, and ending in the crowning victory of Blenheim on 13th August; and the march of the Prince of Hesse, rarely equalled for rapidity and execution. The first was commenced on the breaking up of winter quarters, the troops returning in the autumn during which they covered 1,176 miles (Millner)."

Now Gore bases his statement on Millner. Who, then, was Millner? He was a sergeant in the Royal Regiment of Foot of Ireland—in other words, the Royal Irish Regiment—who kept a journal and published it in 1733, and the following extract tells us of the origin of Gore's statement as modified in Colonel Garrison's notes:

"The tedious but ever glorious, memorable and victorious campaign of 1704 was in length 30 weeks and one day; commenced the 24th day of April and ended on the 20th November; of which our Corps with the Grand Army, and apart, to, in and back from Germany march'd and sail'd ninety-one days and therein three hundred and ninety-two leagues or eleven hundred and seventy-six miles English."

in the second over forty days; it was a case of double pneumonia, the right side being affected first. When I saw him first on May 23rd, 1923, he had a fever of 39° C., a very severe stitch over the right side, and a dry cough: physical examination was positive as to lobar pneumonia. I again prescribed the same treatment. On May 26th I was called to see him, when I found him sitting up in bed with a smile; the fever had dropped the next day, cough was easier, but every now and then he spat pure blood, which continued for about a week, but later it stopped. He is at present as healthy as ever.

These and many other experiences cause me to believe that the above recommended treatment is more than worth while trying, especially so if started early enough.—I am, etc.,

Y. H. DJANIAN, B.A., M.D.,

Instructor in Parasitology and Materia Medica,  
American University of Beirut (Syria).

July 4th.

SIR,—May I renew the appeal published in your issue of November 18th, 1922 (p. 1000), by Surgeon Commander R. J. G. Parnell, R.N., and others, that a trial shall be made of Sir Archdall Reid's formula (aspirin gr. x, pulv. ipecac. co. gr. v, and phenacetin gr. v) in the treatment of small-pox?

Like the signatories of that appeal, I have employed this particular combination of drugs in the treatment of many different fevers and inflammations, and in more than one personal illness. My experience has always been the same—natural sleep, sweating, quick relief from feelings of prostration, and, relatively speaking, a short and mild illness.

I am convinced that Reid's explanation is correct—that the toxins of disease are largely eliminated in the sweat; that the toxins tend to paralyse the sweat centre and so put the pathogenic organisms in a position of advantage; and that the drugs in this formula, acting together, tend to deparalyse the sweat centre. The amount of sweating caused by it is always proportionate to the height of the fever. If fever returns, as it may do again and again, each dose is followed by proportionate sweating. When there is no fever little or no sweating follows the dose. The heart and respiratory centres are quite unaffected.

I share fully the opinion expressed by Surgeon Commander Parnell and his co-signatories—

"Our hopes, we may almost say expectations, are that, if the treatment be employed early in the disease, vesication may be prevented; or, if not vesication, pustulation; or if not the prevention of pustulation, at least a mild attack may be secured" [in small-pox].

In this connexion may I point to the highly significant letter published in your issue of December 2nd, 1922 (p. 1097) by Captain Gelston Atkins, R.A.M.C.? As stated by Reid, the surest proof of the truth of a supposition is that it bestows the gift of prophecy.—I am, etc.,

W. BASTIAN,

Surgeon Commander, R.N.

July 7th.

### THE EFFECT OF HEAT UPON OPERATIONS FOR EXOPHTHALMIC GOITRE.

SIR,—Mr. Walton's paper (June 23rd, p. 1045) shows an interesting way the influence of mere physical means—for example, atmospheric temperature—upon operations which affect the thermal equilibrium of the body. The increased mortality in operations upon the thyroid gland in the summer months suggests the use of cooling treatment in the pre-operative period. May I record two observations on the effect of cold in Graves's disease which made a strong impression upon my mind?

1. A man in middle life, with acute exophthalmic goitre, recovered from all serious symptoms in three months spent in the north of Scotland, partly in a tent on the open moor, with persevering cold sponging. He died seventeen years afterwards of heart failure.

2. A woman of 50, similarly affected and in an almost intolerable condition of heat, spent two hours daily in salt baths at 83° F. at Eastbourne, and proceeded afterwards to the Shetland Islands. After a second summer similarly spent, all her symptoms subsided, and she is now, twenty years later, in fair health.

No doubt many physicians could quote similar cases, showing the good effect of cool and breezy climates, with or without the temporary climate of cooling baths, in allaying excessive heat production in Graves's disease.

The risk of operations upon persons with deficient body warmth can, of course, be lessened by proper application of heat. In the same way, the contrary condition, sometimes described as thermal debility or partial heat-stroke, is successfully treated by graduated and prolonged applications of cold. If the increased summer mortality of operation be due to heat, one might expect it to be prevented by a preliminary course of cooling treatment.—I am, etc.,

London, W., June 27th.

R. FORTESCUE FOX.

### VACCINATION PROPAGANDA.

SIR,—A leading article in the JOURNAL of July 14th, under the heading "Vaccination Propaganda," discusses what has been done in this direction up to date, and states that the following steps have been taken: The issue of tracts, pamphlets, and leaflets by the Jenner Society, and one tract issued by the Ministry of Health to be obtained at the price of 3d. net, which, as you say, is not popularly known and probably very few outside the medical profession know of its existence. Compare this with the activities of the Anti-Vaccination League, and I don't see how one can be surprised at the low percentage of vaccination in proportion to births.

I maintain that the whole procedure of propaganda by leaflet, pamphlet, or tract is useless, especially if one has to go out of one's way and spend 3d. on it. The people who have to be educated by propaganda are the clerk, the working man, the small tradesman, and the like, who generally have no time or inclination to read unattractive tracts or pamphlets, and the only way, in my opinion, to drive home the importance of vaccination is to appeal to him through his sense of vision, and to do this at the time of his relaxation and in his home; and the best way to do this is the following:

A.

1. Have large illustrated posters depicting a man lying in bed suffering from confluent small-pox, the more ghastly-looking the better, with a footnote pointing the moral, such as: "What may happen to you if you do not get vaccinated."

2. Two faces of a beautiful woman—(a) vaccinated, without blemish; (b) not vaccinated, pitted all over and with a blind eye. ("Look on this picture, and on this.")

3. (a) Picture of a child blinded and pitted all over the body (non-vaccinated). (b) Picture of a child with a clear skin and perfect vision (vaccinated). ("Which would you rather your child should be like?")

B.

Have the various cinemas show films depicting the above or kindred pictures, but with more elaboration and explanation in the letterpress accompanying each, as here the people have more time to read about it, and end up the series with a brief film showing the process of the preparation of lymph, and expatiating on its harmlessness owing to the extreme care that is used to ensure its sterility.

The good work could be carried on in the home, as I am sure the great illustrated daily papers would reproduce the above, and the facts would be again impressed on the family and so help to drive one more nail into the coffin of the Anti-Vaccination League.—I am, etc.,

V. ST. JOHN CROLEY,

L.R.C.P. and S.Ed., D.T.M. and H.Lond.

Budleigh Salterton, July 16th.

SIR,—A fortnight since I was asked to judge at a baby competition among children up to 5 years of age. Vaccination was a point for which I gave a mark. Out of 222 children, only 54 had been vaccinated. The following excuses were given: Fathers objected to it being done on account of their having themselves had bad arms. The mothers in many cases had arranged with the officials for the vaccination, but had not turned up.

The outcome of this neglect will, I fear, be disastrous if an epidemic arose.—I am, etc.,

London, E., July 12th.

M. CURSHAM CORNER, J.P.

### FREEDOM OF NEGRO RACES FROM CANCER.

SIR,—One of the most lively impressions present to the mind of the medical worker in Nigeria after two or three years of routine work among the people is the apparent rarity of carcinoma. Personally, I have been looking out for it on the spot for some twenty-two years; and my

marked depression in the size of the contractions. When, however, the change was made slowly, the alteration of size was either absent or much less marked, and the effects on the size of the contractions could be more readily noticed. Passing from neutrality towards the acid side an increase in the height of the contractions was frequently observed, before the depression, which occurred in the neighbourhood of pH 6.5, appeared. Passing to the alkaline side, there was again a gradual depression of the contractions as the pH approached 8.0. After depression by either acid or alkali, a change in the reversed direction improved the contractions; in other words, the intestine beat best in a medium of which the pH was near 7.9. Experiments were also made on isolated rings of the inner part of the tracheal muscle of the ileum, into which nerve cells are considered to penetrate. No alteration of tone occurred in response to changes in the pH of the surrounding medium; but an acid reaction slowed the contractions. Underhill considers it possible that the alterations in tone were due to an influence upon the nervous structures, while the alterations in rate were an effect upon the muscle fibres themselves.

Dr. J. V. Walsh (Research Scholar) has performed a large number of experiments to elucidate the differences between individual colonies of a pure culture of certain members of the intestinal group of bacteria. These variants are of two types and have been designated "smooth and rough." Experiments to ascertain the conditions governing the appearance of the rough forms had reference to the influence of growth in agar and broth. The work is incomplete and conclusions cannot be drawn at this stage, but the experiments show that a definite cycle of changes takes place, the rough forms appearing after varying times of incubation, and increasing to a maximum followed by a sudden drop and disappearance. An experiment to endeavour to maintain rough forms in a stable condition resulted in the observation that it is as possible to do so by transferring colonies from agar slants to agar-plating without passing through broth.

#### GRANTS.

Dr. A. Courton has investigated the hydrolytic activity of the serum of different animals on maltose. He has found maltase present in the serum of the dog, cat, guinea-pig, rabbit, and man. He has further noted a great variation in enzyme activity from dog to dog under various modifying conditions, but marked stability for the individual. In a subsequent series of experiments he has shown that the enzyme maltase in the blood of the dog exhibits from animal to animal a constant optimum temperature of 55°C., at which its action is most potent. This is in contrast with the variability which characterizes the actual amount of enzyme present at any time in the blood of different animals. Full details have been published in the *Biochemical Journal*, vol. 15, 1921, p. 460.

Dr. M. Corvax has tested the value of a bacterial vaccine lymph which he has prepared. The lymph, an be prepared in the short period of five days, and the special bacterial material employed is brilliant-green, which at the end of the period is converted into the colourless and inactive leuco-compound by addition of sodium hypsulphite. The leuco-compound is comparatively inert in bactericidal and vaccinal action, the potency of the lymph being retained at a temperature of 4° to 6° C. during a period of two years. Subcutaneous injections of the lymph were made in 35 cases. In the unvaccinated cases the onset of local reaction occurred in 5 to 10 days, in vaccinated cases from 6 to 9 hours only. There appears, therefore, in the case of vaccinated persons to be a clear gain of 5 days in the onset of the reaction as compared with vaccination by skin scarification. Further experiments were made to ascertain how far inoculated animals would tolerate intraperitoneal injections of fully potent lymph, and the degree of immunity attained as shown by subsequent refractoriness to vaccination of the cornea or skin. It was found that both eye and skin eruptions were refractorily modified if not altogether abolished.

Dr. E. P. Porton (Research Grantee) has shown that distension of the stomach is an important element in the production of pain in cases of gastric ulcer. The experiments consisted in careful distension of the stomach with air introduced through a soft rubber tube and under measured pressure. Further experiments were made by introducing bags containing water or air, connected with a recording apparatus, into the oesophagus, stomach, duodenum, or jejunum. It was shown that pain in the upper alimentary tract was associated with movements in the duodenum, or jejunum. It was also shown that pain was abolished by a successful contraction of the viscera. It was felt during the relaxation of the muscle after contraction. Pain is felt during contraction if the latter is not effective. Dr. Porton read a paper before the Medical Section of the Royal Society of Medicine on January 25th, 1921.

Dr. J. St. G. Watson, who has investigated immunological factors in pregnancy at the Thompson-Lates Laboratories, University of Liverpool, has submitted a report on the complement-oxidation reactions of pregnancy. The conclusions are in the main negative. Professor A. W. Sney has completed his research, the results of which were set out in a joint paper by him and Professor Swale Vincent, published in the *British Medical Journal* of March 4th, 1922, entitled "The function of the chromophil tissues in relation to splanchic stimulation."

## Obituary.

ETTIE SAYER, M.B., B.S.LOND.

PROLONGED ill health, the warnings of which were persistently ignored by one always eager to forget herself, resulted, on July 7th, in the death of Dr. Ettie Sayer in her 48th year. Many societies and institutions, and even more individuals, will mourn the loss of a woman who was always generous with her help and advice—generous, unfortunately, to a degree amounting to self-neglect.

Ettie Sayer was born at Bacton, Norfolk, and received her medical education in London, studying during the early part of the course at University College, and completing it at the Royal Free and Queen Charlotte's Hospitals. She graduated M.B., B.S.Lond., in 1899. Her first house appointment was at the Tunbridge Wells Eye and Ear Hospital. In 1900 she went to South Africa as physician of the Cowley Mission to Mohammedan and Kaffir Women, and was later appointed Plague Officer by the Cape Government. During the South African war she worked in the concentration camps, and was also one of the few who visited the lepers on Robben Island.

On her return to England Dr. Sayer was appointed Assistant Medical Officer to the Education Department of the London County Council. She was one of the first women to do such work in the days before full-time officers for medical inspection of school children were appointed. There are so many men and women doing this work, which is now so efficiently organized, that it is not easy to visualize the difficulties which beset a pioneer. Always enthusiastic and zealous, Dr. Sayer accomplished her difficult task with the utmost conscientiousness, and by her personal charm endeared herself to her superior officers and subordinates alike. Dr. Sayer was particularly interested in feeble-minded and morally defective children. She was consulting physician to the National Society for the Welfare of the Feeble Minded, and wrote papers on morally defective school children. She was a Fellow of the Royal Society of Medicine and Honorary Medical Officer to the Society for Distressed Gentlefolk.

Recently Dr. Sayer interested herself in electro-therapeutics and was a Fellow of the American Electro-Therapeutical Society. She wrote papers on the effects of electric currents on blood pressure and compiled a most useful textbook for nurses on medical electricity and light.

GEORGE JOHN MURIEL, M.R.C.S.Eng., J.P.,

Consulting Surgeon, Whitehaven and West  
Cumberland Infirmary.

We regret to record the death, in his 81st year, of Dr. George John Muriel, J.P., of Whitehaven. He was born in Ely on September 4th, 1842, and was the youngest son of the late John Muriel, F.R.C.S., D.L., J.P., of that city. The Muriels have practised in Ely and the Eastern Counties for several generations. George John Muriel was educated at Epsom College (being one of the earliest pupils there) and at Guy's Hospital. After acting as assistant at Whitehaven from 1866 to 1868 he began to practise on his own account at Alrewas in Staffordshire. On the death, however, of his former principal at Whitehaven he returned to that place, where he resided for the rest of his life. He was appointed to the honorary staff of the Whitehaven and West Cumberland Infirmary in 1872 and became consulting surgeon in 1900 when he retired from general practice, being succeeded by his second son. He was President of the Border Counties Branch of the British Medical Association in 1898 and the first Chairman of the West Cumberland Division under the new constitution of the Association. To celebrate his long connexion of fifty years with the Whitehaven Infirmary he was presented with his portrait two years ago. The large attendance at the funeral, despite the fact that he had retired from practice so long ago, showed the respect with which he was regarded by all classes in the town and district, and by his medical colleagues, all of whom were present. His wife died two years ago; he is survived by all his family (four sons and three daughters) except one son who died in 1878.

## UNIVERSITY OF SHEFFIELD.

THE University Council has appointed Mr. Denton Guest, M.B., Ch.B., to the post of Assistant Bacteriologist.

## NATIONAL UNIVERSITY OF IRELAND.

AT the meeting of the Senate on July 6th Dr. Denis J. Coffey, Pro-Vice-Chancellor, was appointed as Representative of the University on the General Medical Council.

Dr. William M. Crofton, University Lecturer in Special Pathology in University College, Dublin, whose tenure of office was about to expire in accordance with the statutes, was reappointed.

The results of the recent summer examinations were considered and passes, honours, etc., were awarded in connexion therewith.

## LONDON SCHOOL OF TROPICAL MEDICINE.

THE following were approved at the examination of the London School of Tropical Medicine, held at the termination of the seventy-second session (April to July, 1923):

E. Peterson (Duncan Medal), \*A. R. Baldwin, \*F. McCallum, \*E. Pampana, \*A. Salama, R. S. Aiyar, M. M. Khan, W. J. E. Phillips, J. L. Robello, A. N. Kingsbury, F. R. Thornton, J. W. F. Albuquerque, N. S. Sethi, A. J. Keovil, D. J. Valentine, A. N. Thomas, L. S. Chatterji, K. K. Shoni, W. Simmons, H. Sheinbloom, M. R. Goverdhan, S. W. Hardikar, H. Morrison, G. Gollerkeri, K. S. Thakur, C. McIver, E. C. Cousins, G. W. S. de Sarani, J. G. Dunlop, B. W. Dakers, J. R. Chandhri, A. M. MacRae, P. Couacaud, K. T. Thalan, J. B. S. Baxter, L. Ray, M. K. Gopala-Pillai, K. Singh, E. Sutcliffe.

\*With distinction.

## The Services.

## DEATHS IN THE SERVICES.

Colonel John Girvin, Army Medical Staff (retired), died in a nursing home on June 25th, aged 61. He was born at Seaforth, Lancashire, and received his medical education at St. Bartholomew's Hospital. He entered the army as surgeon on July 27th, 1887, and attained the rank of lieutenant-colonel on February 9th, 1912, and became colonel in the great war promotion of March 1st, 1915. He served in the Sudan campaign of 1898, receiving the medal and the Khedive's medal; and in the recent war served as D.D.M.S. in Gallipoli and Egypt. Sir Robert Armstrong-Jones in the course of an appreciation writes: He came of a well-endowed Scottish family and the racial character of tenacity, caution and commonsense were innate to his nature. Although himself an Anglican, it was probably his paternal Presbyterian sympathies that caused him to regard ceremony with suspicion and to believe that truth and reality dwelt rather in the informal and the simple. He was born in 1861 and was one of a large family of successful brothers and sisters. It may be truly said of him that his mentality had no angles, and apart from the bent of his mind the upbringing he experienced caused him to be tolerant, receptive, and sympathetic. After an apprenticeship at Dorking—an unusual occurrence even in the eighties—he entered St. Bartholomew's Hospital as a student in 1882, where he developed a friendship with Sir D'Arcy Power, Sir William J. Collins and the writer, which lasted a lifetime. Shortly after his first term of service in India he was ordered to Egypt, where he remained for three years during the Egyptian war; after the war he served in Cyprus, where he received the special thanks of the Governor for his voluntary work for the civilians and peasants. Later, he was appointed to the medical charge of the Guards in Wellington Barracks, and for over two years was secretary to Sir A. T. Slogett. He was afterwards sent specially to Sierra Leone on the West Coast of Africa, and later to India, a second time, as senior medical officer at Hyderabad, Scinde. He returned home in 1913 and later helped to form a new hospital for Gallipoli, being there appointed, first, as chief in charge of the advanced base hospital, and secondly, as D.D.M.S. After Gallipoli he again served in Egypt, where he was in charge of the 27th General Hospital. Whilst in India he married Miss L. Smith, whose mother was well known in Poona for her public services. Their only child, a son, educated at Haileybury, was a most promising young officer in the 7th Royal Dublin Fusiliers; he died from wounds received in Salonika—a blow from which Colonel Girvin never recovered, his health gradually failing from that date.

for the bone which would limit the formation of exudation, granulation, and fibrous tissue. It could not itself prevent adhesions. It must be kept firmly in position. There were two conditions essential to provide a new synovial sac—there must be sufficient space between the bone ends, and there must be a gliding movement to stimulate the walls of the cavity to secrete a supply of fluid and to prevent fibrous organization. Attempts to provide a new synovia of oil or liquid paraffin had been unsuccessful. Continuous traction on the new articulation and early voluntary movements were the essentials of after-treatment.

In the elbow the indications included all cases of bony ankylosis free from active infection except those in which a strong useful arm was present in a labouring man. The best operation for the elbow was to preserve the whole width of the humeral condyles and to cover the bone with a free flap of fascia lata.

In the hip three different types of operation must be considered: For simple ankylosis an osteotomy of the neck of the femur with the interposition of a flap taken from the trochanter or from the capsule; for massive hypertrophic ankylosis a subtrochanteric osteotomy with the interposition of a fascial flap forming a saddle-shaped joint; for osteoarthritic excision of the head of the femur.

In the knee the importance of stability and painlessness rendered unjustified any mobilizing operation if the joint was fixed in a good position. It was only in the case of ankylosis of both knees that arthroplasty could be considered. The use of free fascia to cover the lower end of the femur, the preservation of the lateral ligaments, and the use of a jointed knee cage for some months after operation were the special points on which stress must be laid. If lateral mobility persisted then the lateral ligaments must be reinserted at a second operation.

Dr. Petti of Bologna then gave one of the most striking demonstrations of the Congress. He illustrated his remarks on the knee by showing cinematographic films of patients, who had suffered from ankylosed knees walking, running, and cycling many months after operation. Finally, he produced patients with easily flexible knees. There were, he said, general and specific indications for arthroplasty. The general ones related to: (a) The state of the patient, his age, his mental and social conditions, and his occupation. Arthroplasty was a long and tiring, maturing operation. It should, therefore, only be done on patients who were favourably disposed from the point of view of organic resistance. The best age was between 20 and 50. It was absolutely indispensable that the patients should whole-heartedly co-operate with the doctor. He never operated on subjects hypersensitive, neurotic, irritable, or mentally deficient. Nor should an operation be done when the patient's means did not permit a long stay in hospital. The profession or calling of the patient must also be considered. (b) The etiology, pathology, and anatomical conditions of the ankylosis. In ankylosis consequent upon infective arthritis the most amenable to correction were those following an acute inflammation. Osteous ankylosis was easier to correct than fibrous. Ankylosis of tuberculous origin should only be operated upon as an exception. Good results might be obtained from cases of war ankylosis, arthritis deformans, or polyarticular arthritis. Operations should never be done less than a year after the disappearance of the more striking symptoms of the stiffening process. There were absolute indications for arthroplasty in ankylosis of the mandible, in bilateral ankylosis of the hip, in ankylosis of the elbow in extension, in polyarticular ankylosis. In cases of bilateral ankylosis of the hip it was generally wise to operate only on one side. As good results could easily be obtained in the knee as in the elbow. Incisions should be made in order to obtain a wide field of observation. An exact adjustment of the epiphyseal extremities of the bone should be made with files and drills; they should be covered with free flaps of fascia lata. The first passive movements should be begun twelve to fifteen days after the operation. Thermotherapy in the production of active hyperaemia should not be neglected. After arthroplasty of

the lower limbs patients should not be allowed to walk before the thirtieth day. The new joint appeared as the result of function. Interposition of aponeurotic flaps greatly helped post-operative treatment. Their action was only temporary. It did not therefore matter that they would not keep indefinitely vital. The growth of a new joint was very slow. Examined long after operation it showed anatomical conditions very like a normal articulation. Functionally these cases did very well, becoming neither arthritic nor deformed. Their functional resistance was high for many years.

Dr. Petti on his brilliant demonstration. He stressed the point that an excision was not an arthroplasty, for which special highly developed technical skill was especially necessary and for which judgment in the selection of cases was very difficult. Ankylosis was due to an infection or to trauma. Gonococcal metastasis usually occurred in eighteen to twenty days, staphylococcal in ten to fourteen days, and those due to streptococci and the colon bacilli in eight to ten days. The synovium was first affected and, long after, the cartilage. Infections, acute or chronic, did not constitute a contraindication to arthroplasty provided that the process had not been tuberculous and was not active. A tuberculous joint, even when ankylosed firmly, might retain small walled-off foci through life, and therefore, except in cases of great rarity, should be considered a direct contraindication to any arthroplasty. Occasionally deformity of such a degree was present as to warrant correction before an arthroplasty was attempted. The hip, ankylosed in marked flexion and adduction, should be corrected by a preliminary procedure. Similarly marked flexion of the knee might necessitate treatment before the arthroplasty was done. Indications for the operation were: two stiff hips, indicating arthroplasty in one or both; two stiff elbows, two stiff knees, again indicating arthroplasty in one at least. Combinations of hips and knees very definitely indicated an attempt to mobilize one or more joints. Amongst the lesser joints were stiff shoulders, fingers, wrist (a very rare subject for the operation), and the jaw. The speaker then surveyed the development of his work with chromiumized pig's bladder to Dr. Baer for his work with chromiumized pig's bladder and to the late Dr. J. B. Murphy for his advocacy of the podonunciated flap. Free fascia in the hands of Petti and Dr. MacLachlan had been most successful. Dr. MacLachlan made a comprehensive statement regarding each joint, stating indications and contraindications for operation, and described the general methods of treatment. With regard to the knee, arthroplasty should only be very cautiously advised in cases of ankylosis of one joint, in spite of recent advances. Lateral stability and security were here of first importance. Dr. Sarrt of Lyons said that surgical mobilization of ankylosed joints had as yet been little used in France. The reason was that they continued to use Oliff's mobilizing resections. For the shoulder, elbow, and wrist the mobilizing resection gave excellent results, but to obtain them great tenacity and a great deal of patience were required, not only from the surgeon, but also from the patient. Arthroplasty was unquestionably an improvement and gave better results. For the hip the mobilizing resection was sometimes indicated, as in the case of large bony fusions, rendering surgical mobilizing and interposition difficult and dangerous. Apart from these cases, arthroplasty was here also an improvement. In the hip and knee the operation opened a new chapter in articular surgery. Resection for ankylosis had become a secondary method, or in those rare cases where the state of the bony or, more rarely, the soft parts of the articulation made an attempt at mobilizing the joints unwise.

Sir William MacEwen remarked that Dr. Murphy had once said that all excisions resulted in nail joints; they knew now that if intracapsular incision was made no nail joint need result. He had been glad to hear that the function of the various flaps used was that of a lining membrane. He had always said that the peritoneum was only a limiting membrane.

Mr. Exarsie of London said that in any new operative procedure it was important to know how to carry out the technique and when to utilize it. Arthroplasty differed

THE KING has granted a Royal Charter of Incorporation to the Royal Westminster Ophthalmic Hospital.

DR. S. GORDON LUKER will give a lecture in the anatomical theatre of the London Hospital Medical College on Tuesday, July 24th, at 4.15 p.m., on a new method of treatment of puerperal sepsis. The lecture is intended for senior students of the hospital and post-graduates, to whom a cordial invitation is given.

THE 19th South African Medical Congress will be held next year in Grahamstown, Cape Province, when the hosts will be the medical practitioners in Grahamstown, Port Elizabeth and Uitenhage. The president of the congress will be Dr. F. G. Dru Drury, of Grahamstown.

THE Lord Mayor of London (Aldermah Edward O. Moore) has consented to act as the honorary treasurer of the Endowment Fund of the People's League of Health. Cheques should be sent to him at the Mansion House.

THE Military Hospital, Rochester Row, Westminster, has been closed and the work transferred to the Royal Herbert Hospital, Woolwich.

THE well known physiologist, Professor J. P. Langlois, of Paris, has recently died at the age of 61.

THE United States Public Health Service has declared the port of New Orleans to have been completely free from any trace of bubonic plague for the past two years, and will now entirely withdraw its staff; a test of 200,000 rats caught in that period revealed no trace of infection. Precautionary work in rat eradication and tests will in future be undertaken by the city board of health.

DR. GELLÉ, a well-known French pioneer in otology, and one of the founders of the Société Française d'Oto-rhino-laryngologie, has recently died at the age of 80.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

### QUERIES AND ANSWERS.

"J. D." asks for advice in the treatment of an old lady who suffers from intense burning of the feet at night, so severe as to prevent sleep. Many remedies—mostly external—have been tried in vain. She has a cardiac lesion, and the loss of sleep is a serious factor.

### LETTERS, NOTES, ETC.

#### DEVICES FOR INVALID COMFORT.

SIR CHARLES BROWN, M.D., of Preston, who is nearly 87 years of age and has been all but confined to his dining-room (where he sleeps) for the past eighteen months, has devised a combination of two chairs with simple accessories, which invalids should find useful. The chief item in the combination is an American rocking chair, which can be fixed at different levels by a wedge; with it may be employed a companion chair which, with a flat cushion made to fit its seat and a hot-water bottle, makes a comfortable bed for the heels; a pulling-up cord controls the position of the hot-water bottle. The bedclothes are fixed to the back of the companion chair and are arranged somewhat in the form of a tube or sleeping bag. A simple table for meals completes the outfit.

### TEETH AND SUGAR.

MR. C. N. PEACOCK, L.D.S. (Bedford), writes to suggest that practically all decay of children's teeth is to be laid to the charge of "so-called sugary foods": he inquires what daily amount of sugar should be included in a well-balanced diet for a child. Our correspondent points out that raw flour, tragacanth, and glucose which sticks to the teeth, are used in the manufacture of sweets. The child who eats them coats his teeth with an ideal paste for the production of dental caries. The suggestion is that the Sale of Food and Drugs Acts might be amended, but we are inclined to think that education of the parents both on this point and on the amount of sugar a child needs in its daily diet (it may be none is needed) would be more effective. It is a matter that might well be discussed at congresses of child welfare.

### THE CAUSATION OF CANCER.

DR. A. S. DUTTON (London) writes: The circumstance that friction by the clothes of a chimney-sweep, when of a rough corduroy type or of other materials, during their employment most of each day doubtless considerably enhances the irritating effect of soot, and that the irritation by the latter is more or less constant, appears to account largely for cancer of the scrotum in man, and afford reasons for its non-production by the rubbing in of soot in rabbits, rats, and mice, as referred to in Dr. A. Leitch's article in the BRITISH MEDICAL JOURNAL of July 7th (p. 1). Apart from the effect of clothes, a reason for the scrotum being the site of cancer in sweeps and not other parts of the body may be that the scrotal rugae afford an especially favourable site for the lodgement of soot, which—although washing takes place, unless this is effected to the extent of full immersion in water and also the vigorous use of soap—tends to accumulate to a certain extent among them in some cases without being at any time wholly removed, and therefore forming a practically constant source of irritation. The wearing of suitable overalls which prevent soot reaching the scrotum would apparently prevent the occurrence of sweeps' cancer. Similarly, if tar, pitch, and paraffin were prevented from reaching the scrotum of workers in these industries by suitable protective material, cancer of this structure occasioned by them should be eliminated.

### BREEDING RATS FOR FEEDING EXPERIMENTS.

IN order to maintain a collection of rats suitable for dietary experiments considerable wisdom has to be shown in the selection of the stock and precautions taken against parasite and bacterial infections. Professor V. H. Mottram and his co-workers have described in a recent article (the *Biochemical Journal*, vol. xvii, No. 2, 1923) the method they adopt; this report will be of value to those engaged in similar work, and certain of their conclusions are of general biological interest. They have found that the best stock is obtained by intensive inbreeding from one or more pairs of adult animals which have been obtained from a good source when quite young and kept on a good diet under strict observation. There is no evidence that there is any danger in inbreeding when the original stock is good—in fact, it is of advantage in stabilizing the stock and limiting variations. The mixed stock from dealers is often infected with disease which may not betray itself early in life and is almost impossible to eradicate. Probably most of the failure in rat breeding is due to housing; in order to avoid such diseases as pneumonia the animals should be housed at a temperature of 65° F., with no more than 5° variation in either direction. There is no justification for the widespread belief that rats will not thrive in metal cages; they are easier to clean and they have been used by these workers for rearing generation after generation from birth to adult life. The stock should be fed on diets containing bread and milk and kitchen scraps with a high percentage of protein and fat, and the mothers should receive during lactation liberal supplies of bread and milk.

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 27, 30, 31, and 33 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 32.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 6  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 15 0 |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded. Advertisements should be delivered, addressed to the Manager, 429 Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

might last from eighteen months to several years. Two cases were to be distinguished. In war surgery, as well as in civil surgery, immediate suture of the nerves should normally be completely successful. Delayed surgical treatment might give good functional results in 40 to 50 per cent. of the cases, according to the nerves, which it had been performed from one month to two years after the wound. After that time it should nevertheless be tried; it might be successful, but they agreed with most medical authorities that there was less chance of its succeeding. Nevertheless, the surgical treatment of the big nervous trunks was not by any means illusory if it was carefully and systematically practised by specialists who were equipped for that purpose, and when the patient could be kept under prolonged observation. In those circumstances satisfactory results might be obtained. Dr. Frazer of Philadelphia stated that, of 208,000 casualties there were 3,500 peripheral nerve injuries. It was estimated that no operations on these conditions were performed. All were done by specially qualified men at twelve peripheral nerve centers in the United States. It was the general practice to postpone operation until three months after the wound had healed. To wait for spontaneous regeneration longer than six months was not considered justifiable, although it is well known that the first clinical signs of spontaneous regeneration might be deferred much longer. He had seen one case of musculo-spiral paralysis in which the first sign of the return of voluntary motion did not appear till twenty-one months after injury. During the period of reconstruction he relied upon the various signs of recovering function to determine whether spontaneous regeneration was in process or not—such as a contraction of the field of sensory loss, the return of muscle tone, the changing electrical reactions, and the advancement of Fine's sign. This latter, however, was not an infallible guide. In 1922 a more accurate clinical method of determining the early recovery of a degenerated nerve was elaborated. With the aid of a specially constructed electromyometer the nerve muscle complex was found to disappear as early as the fifth day after the nerve was cut, and it began to appear from one to six months before a readable response, from one week to three months before voluntary contractions, and up to five months before contraction of the anaesthetic area. If, six months after injury, the lesion was stationary, when there was evidence of complete anatomical interruption, when there was no interstitial neuromatosis in continuity without imperfectly conspiciated, operation was recommended. The damaged nerve should be resected sufficiently to expose normal fasciculi above the seat of fibrosis. Coaptation was effected with six to eight epineural silk sutures, and, when required to relieve tension at the line of suture, a stay suture of catgut was employed. Partial resection was rarely indicated. A nerve bed free from scar tissue was the line of suture with any foreign tissues—fascia lata, vein, or Cargill membrane—had been generally condemned. With regard to bridging defects, primary nerve stretching, nerve transposition, and the two-stage operation were the selected methods, in the order named. The two-stage operation virtually eliminated the necessity for transpositions. Nerve distortion must be avoided. A sensory fasciculus could not function as a motor fibre, and vice versa. With regard to end-results, he presented a table of 487 operated cases, including 132 neurotises, 350 neurothaphies, and 14 transplants.

## 50. The Use of Simple Cow's Milk Mixtures in Infant Feeding.

E. P. BAUMANN (*Med. Journ. of South Africa*, March, 1923, p. 197) gives a method of preparing cow's milk mixtures in which the proportion of the different ingredients is based on their calorific values, and not, as is customary, on the percentage as compared with human milk. The modern tendency, he states, is to discard the complicated methods involved in the use of top-milk and percentage formulae and is a reversion to early days. The method consists, roughly, in diluting with plain water, and only carbohydrate is added. This gives a mixture of high sugar, relatively low protein, low fat, and relatively low salts—not, he admits, an accurate or scientific mixture if taken on the percentage scheme, but based, nevertheless, on physiological needs and a knowledge of metabolism. A supply for twenty-four hours is made up at one time, the required amount being estimated in calories, not in ounces. The "maintenance requirement" of an average healthy infant is forty to fifty calories for every pound of body weight. Tables are given showing the approximate calorific values of 1 ounce of various foods, and among these cow's milk represents 20, human milk 20, and sugar 120 calories. Thus for a healthy infant of 4 months weighing twelve pounds a total of 540 calories would be required, and could be made up of milk 18 oz. (360 calories) and sugar  $1\frac{1}{2}$  oz. (180 calories). Further formulae are given from which the size, number, and necessary dilution of the feeds can be calculated. The author does not claim that the method will be found to answer in every case, but he lays stress on the fact that every food mixture, however prepared, must be regarded as being in the nature of an experiment. He further recommends that the ultimate composition of mixtures should be checked in percentages, on which basis feeds prepared as above would be represented as follows: carbohydrate 7.7 per cent., fat 2.4 per cent., protein 2.1 per cent., salts 0.45 per cent. The article contains other general observations of interest in connexion with infant feeding.

## 51. Heliotherapy in Tuberculosis.

FERRANNINI (*Rif. Med.*, May 14th, 1923, p. 157) speaks with chastened enthusiasm of the good results obtained by this form of treatment in internal manifestations of tuberculosis. After a preliminary historical survey, with especial reference to the work of Sciascia, he classifies the therapeutic effects of light in their order of merit as sunlight, Flinsen lamps, quartz lights,  $\alpha$  rays, and lastly, the incandescent lamp. In heliotherapy considerations of climate, atmosphere, place, etc., have all to be reckoned with. For various reasons mountain heights seem to give the best results. The treatment should not be continuous, but varied with interruptions or even change of climate. Authorities differ as to the value of pigmentation as an index of progress; some say good pigmentation is a favourable sign, others the reverse, or that it is of no value as a prognostic sign. In any case, says the author, it is always well to expose the body in sections and not the whole at once. Protection against excessive solar erythema is necessary. In addition to any direct curative effect, heliotherapy is useful as a prophylactic. The author suggests a new reading of the old adage "where the sun comes the doctor never goes" to "where the doctor comes he brings the sun with him" as part of his therapeutic armamentarium.

## Surgery.

## 52. Experimental Surgery of the Thoracic Oesophagus.

R. T. MILLER and W. D. W. ANDRUS (*Bull. of the Johns Hopkins Hosp.*, April, 1923, p. 109) describe experimental work on the dog undertaken with a view to devising an intrathoracic method of operation applicable to strictures of the oesophagus in man, and in which the causes of previous failure are circumvented or avoided. These causes are stated to be lack of sufficient firm tissue wherein to sink the sutures, which consequently tear out; a fatally high tension on the suture line; and, finally, the frequency with which gangrene results from interference with the circulation where enough of the tube has been freed to permit of room for suture. After resection of the lower third of the oesophagus, the authors found that a much wider gap could be bridged by implantation into the fundus of the stomach than by end-to-end anastomosis. Excellent access was obtained through the eighth intercostal space, and implantation effected on the anterior stomach wall to the left of the cardia. Out of 18 such anastomoses 11 were shown to have resulted in an intact suture line and a successfully functioning union, and the mortality, though high, resulted from conditions in no way concerned with the security of the suture. Three deaths from septic infection are admitted, but it is contended that this risk

could be reduced with experience and improved technique. From dilatation of the stomach (probably the result of section of the vagus nerves) two deaths occurred; the authors suggest that as this is not a permanent effect it could be met in human subjects by prompt recognition and treatment. Diaphragmatic hernia was found to be prevented by accurate stitching of the edges of the diaphragm to the stomach. Owing to tension, end-to-end anastomosis of the dog's oesophagus was found unsuited to bridge a gap of more than 3 cm., and, to meet this, experiments in mobilization of the stomach were initiated. Briefly, it was demonstrated that division of the anastomotic branches of the phrenic artery, the coronary artery, and the vasa brevia permitted the fundus to be mobilized to an extent that would replace most of the thoracic oesophagus in the dog, but that further interference with the blood supply could not be attempted without resultant necrosis of the stomach wall. Attention is drawn, however, to the limitations in this respect imposed by the atrophied stomach of a patient suffering from malignant disease as compared with that of a healthy dog. Histological study having shown that the human oesophagus possesses a well developed submucosa, the observers perceive no reason why, with adequate caution, it should not present as secure a grasp for a stitch as that of the dog. The development of surgical possibilities on the above lines would go far, it is urged, towards elucidating the problems of the present unsatisfactory treatment of cancer of the thoracic oesophagus.

## 53. Trypaflavine in the Treatment of Vincent's Angina.

H. BUSCHMANN (*Deut. med. Woch.*, May 11th, 1923, p. 817) has treated 14 cases of typical Plaut-Vincent angina between October, 1922, and March, 1923. In every case the clinical examination showed the characteristic diphtheroid ulceration, and the bacteriological examination showed the typical spirilla and fusiform bacilli. The following treatment was adopted in every case. A solution of trypaflavine, put up in 10 c.cm. ampoules, was painted three or four times a day on the tonsils, palatine arches, and uvula. Every other hour the patients gargled with a 0.5 per cent. solution of trypaflavine, and they were told that it did not matter if they swallowed some of the gargle by accident. In 13 cases the membranes were discharged, and recovery occurred three to seven days after the institution of this treatment. The fourteenth patient suffered from four different attacks of Vincent's angina; the first two reacted promptly to the treatment with trypaflavine, but on the third and fourth occasions the disease proved refractory to this treatment, and painting with salvarsan was resorted to. The author concludes that trypaflavine is an excellent remedy for Vincent's angina.

## 54. Auto-vaccine Therapy in Oto-laryngology.

G. WORMS and G. DELATER (*Rev. de Laryngol., Otol., et de Rhinol.*, April 30th, 1923, p. 307) are convinced of the value of autogenous vaccines. They had derived most excellent results in cases of furunculosis of the external auditory meatus and the vestibule of the nose. These were mostly staphylococcus infections. One case had a large abscess in the axilla and furuncles of the nasal orifices and eyelids. All kinds of treatment had been tried, but an autogenous vaccine cleared the condition quickly. These cases of furuncle round the nasal, aural, and ocular regions are exclusively due to cutaneous flora—staphylococci—and not to the streptococci and pneumococci of the mucosa. On the other hand, practically all cases of accessory sinusitis and otitis media have an infection of streptococci, in some cases mixed with other strains—staphylococci, pneumococci, diphtheroid and other bacilli. The more chronic condition the more diverse and multiple were the bacteria present. In streptococcus vaccine it appears that the antigenic properties are very quickly lost, and the authors now only prepare six or seven doses at a time, making a new vaccine from a fresh supply of pus when these are administered and the lesion is not cured. Sterilized pus has been administered to animals but not to man, on account of the danger of anaphylaxis from the rich mucus and albumin content of the pus. The disadvantage of auto-vaccines is that in the case of a thin culture several days may be lost before a rich enough growth is obtained to prepare the vaccine. This has been overcome by a method of rapid bedding out of the streptococci on to egg-albumen medium on the slant, and enough bacteria for the six or seven doses can be prepared in twenty-four hours. The original tubes are not used but only the bedded-out colonies. Sterilization is performed with 2 per cent. iodine, which is neutralized with sodium hyposulphite. The vaccine is standardized to 500 million streptococci and 1,000 million of other germs to 1 c.cm. The first dose is 0.5 c.cm., followed by 1.0 c.cm., 1.5 c.cm., and so on every second day. Pain and local inflammation rapidly disappear, but the purulent discharge

RECEPTION AT THE ROYAL COLLEGE OF PHYSICIANS.

A reception for members of the Société Internationale de Médecine was given by the President and Fellows of the Royal College of Physicians of London on Thursday afternoon, July 19th.

The guests were received in the large library by the President, Sir Humphry Rolleston, who was accompanied by the censors, the registrar, and the Harleian librarian. A number of books illustrating the history of anatomy and surgery were placed on view. The library of the College contains an unusually large number of early anatomical and surgical works, and the history of anatomy and surgery from the fifteenth to the nineteenth centuries could be studied in the books exhibited. Special care had been taken to show as many books as possible by day because the exhibition books of this character either have been given to various parts of the human body, anatomists, whose names are remembered to-day because besides the exhibition books of this character other rare books and manuscripts more particularly connected with the history of the College were on view, and visitors had the opportunity of seeing the oil portraits on the walls to the number of some 120, which illustrate the work of many British portrait painters from the seventeenth to the nineteenth centuries.

RECEPTION AT THE ROYAL COLLEGE OF SURGEONS.

A reception was given on July 19th by the President and Council of the Royal College of Surgeons of England in the College, when the guests were received by the President, Sir John Bland-Sutton, and the Vice-President, Sir Berkeley Moynihan, Bt., and Mr. H. J. Waring. The visitors were guided through the museum by the conservator, Sir Arthur Keith, F.R.S.

DEMONSTRATIONS.

During the meeting a number of demonstrations were given, including one by Sir Charles Ballance on nerve suture, and another by Sir Almonro Wright, at St. Mary's Hospital, on the practical application of points mentioned in his address on vaccine-therapy and serotherapy. The members of the Society had the opportunity of visiting various hospitals each morning and witnessing operations.

STUDENTS.

We have received for publication from the Council of British Ophthalmologists the following correspondence which has passed between it and the General Medical Council:

To the Secretary, General Medical Council.

22th March, 1923.

Dear Sir,

The Council of British Ophthalmologists begs to draw the attention of the General Medical Council to the following statement in the final report of the Departmental Committee on "Causes and Prevention of Blindness," which has recently been published:

"We recognize that the inadequate knowledge of diseases of the eye possessed by the large majority of the medical profession is a large measure due to the very limited amount of training in this subject which they receive in the medical schools. With a few exceptions the universities and examining bodies in Great Britain do not require candidates for a qualifying degree or diploma to be examined in ophthalmology. It is true that questions on ophthalmic surgery are occasionally included in a paper or in the oral examination, but these can in no sense be considered as an adequate test of the candidate's knowledge of this subject."

"In our opinion no licence to practise medicine should be granted without satisfactory evidence of an adequate knowledge of diseases of the eye. The supervision of the medical curriculum and qualifying examinations is in the hands of the General Medical Council. This body demands of medical students three months' attendance in an ophthalmic department, but representatives of the majority of this regulation have failed to produce any stronger assistance on more effective training in ophthalmology."

"The Council of British Ophthalmologists is of the opinion that the inadequate knowledge of diseases of the eye possessed by the large majority of the medical profession is a large measure due to the very limited amount of training in this subject which they receive in the medical schools. TEACHING OF OPHTHALMOLOGY TO MEDICAL STUDENTS.

"We recommend that the General Medical Council again be urged to insist that every student presenting himself for a qualifying examination in medicine shall be examined in ophthalmology."

"This recommendation of the Departmental Committee, which was composed of both laymen and medical men, is entirely in keeping with that submitted by the Council of British Ophthalmologists to your Council in 1919 (copy enclosed) in which it was suggested that: "No student shall be considered to have passed the qualifying examination unless he has shown a sound knowledge of practical ophthalmology in an examination conducted by ophthalmic surgeons." The action which your Council took at that time was—

"That every student should be required to attend a course of practical instruction in ophthalmology of not less than ten weeks' duration and that no student should be admitted to the final examination unless he presents a certificate to the effect that he has attended such a course regularly, and that his work in connection therewith has reached a satisfactory standard."

"The Council of British Ophthalmologists wishes to point out that this arrangement leaves it entirely to the ophthalmic surgeon in charge to determine what the evidence of satisfactory work in his department should be, an arrangement which is not considered sufficient with respect to any other of the essential subjects in a student's curriculum."

Further, the Council of British Ophthalmologists has ascertained that in the London medical schools the evidence of satisfactory work is receiving very different interpretations. In one school every student is now required to pass an examination before his certificate is signed, in others mere attendance in an ophthalmic department is recognized as sufficient. This difference in the interpretation of the General Medical Council's requirements causes not only a feeling of injustice amongst the students of the different schools, but is also a standard of requisite knowledge which it sets up, and in placing the responsibility entirely in the hands of the teacher. The experience of the Irish universities and colleges, in which an examination in ophthalmology has been for many years recognized as an intrinsic part of the final examinations for their degrees and diplomas, shows that there is no great difficulty in the adoption of its recommendation would not entail any modification of the curriculum already required by the regulations of the General Medical Council, but only that an effective and uniform test be applied to the knowledge which a student should have acquired in the course of the curriculum."

"The recommendation of the Departmental Committee on the "Causes and Prevention of Blindness," which coincides with the previously expressed views of the Council of British Ophthalmologists, encourages the latter again to urge the General Medical Council to insist by means of an examination in ophthalmology on a uniform standard of knowledge in this subject."

Yours very faithfully,

(Sgd.) J. B. LAWSON, President.

M. S. MAYOR, Hon. Secretary.

General Council of Medical Education and Registration of the United Kingdom.

London, W.1, 5th June, 1923.

The Honorary Secretary, Council of British Ophthalmologists, 69, Harley Street, W.1.

Dear Sir,

I have to inform you that your letter of the 28th March, drawing attention to the report of the Departmental Committee on the Causes and Prevention of Blindness, was considered by the Examination Committee of the Council, and that the greater part of your communication was printed in full in the report made by them thereon to the Council.

This report was considered at the meeting of the Council held on the 1st of June, and I was directed to inform you that it is too soon to judge of the effect of the resolution recently adopted by the Council.

I might add that in regard to the paragraph in the report of the Departmental Committee I was directed to inform the Ministry that on May 25th, 1922, the Council made certain recommendations to the licensing bodies for the improvement of the medical curriculum, one of which was that each student should receive instruction, *inter alia*, in the diseases of the eye, refraction, and the use of the ophthalmoscope. The Council thereby anticipated the wishes of the Departmental Committee as set forth in their report, which was not published until the autumn of that year.

Yours faithfully,

(Sgd.) NORMAN C. KNOX, Registrar.

subsequently showed signs of phlebitis; the presence of a myoma in the right iliac fossa was recognizable. Three months later severe pain was experienced in the region of the myoma, which rapidly increased in size; at the same time a foetid vaginal discharge was noted. The uterus, which was removed unopened, was found to contain a living seven months foetus. The myoma—an interstitial one—was the size of an orange, and exhibited central haemorrhage; the placenta was partially separated in the adjacent zone, and the uterine cavity in this region contained infected liquid blood.

#### 61. Prolongation of the First Stage of Labour.

E. GUEISSAZ (*Gynecol. et Obstét.*, 1923, vii, 5, p. 390) observes that death of the foetus during labour is due twice as frequently to abnormalities of the maternal soft parts as to pelvic contraction or deformity. From an analysis of fourteen years' records of the Lausanne Maternité he draws the following conclusions. Rigidity of the maternal tissues plays the predominant part in abnormal prolongation of the first stage of labour, and is much more frequent in primiparae (128 cases) than in multiparae (22 cases). Advancing age is not the sole etiological factor concerned, and the author believes that an antecedent gonorrhoea is of considerable importance, especially in young subjects; of 30 cases of prolonged dilatation in primiparae aged under 25, more than one-third had gonorrhoea, as compared with 12 per cent. in older primiparae and 18 per cent. in multiparae, and with 2 per cent. among the whole of the mothers of the clinic. Other factors leading to cervical rigidity are pregnancy, nephropathy, and uterine myoma. The other main cause of prolongation of the first stage of labour consists in abnormalities of the uterine contractions, combined frequently with early rupture of the membranes. With regard to the merits of the various forms of treatment for a prolonged stage of dilatation (defined as exceeding forty-eight hours), Gueissaz remarks that over two-thirds of his cases received morphine, which in one-third was the sole treatment; given in the latter half of the second stage it not only diminishes pain, but also improves the uterine contractions. Hot vaginal douches of 30 to 40 litres improved the pains in about one-third of the cases, and, whether given before or after rupture of the membranes, were not followed by increased puerperal morbidity. Immersion in a hot bath for half an hour appeared free from danger, and had a still more favourable influence on the pains. Pituitary extract is not generally to be recommended at this stage, and incision of the cervix, the colpeurynter, and mechanical dilatation are dangerous. Manual dilatation of the cervix should be reserved for cases of commencing foetal distress.

## Pathology.

#### 62. The Influence of Hypertonic Salt Solutions on Granulation Tissue.

W. V. GAZA (*Zentralbl. f. Chir.*, June 2nd, 1923, p. 853) has arrived at the conclusion that the influence of strong salt solutions on granulating wounds is not to be ascribed to an osmotic effect, as commonly assumed, but to ionic action, and more particularly katonic. If the effect were merely osmotic it should not matter which salt were used; in fact, non-electrolytes such as sugar, urea, etc., should act in the same way. He has observed the results of applying 10 per cent. solutions of KCl, NaCl,  $\text{Na}_2\text{SO}_4$ ,  $\text{CaCl}_2$ ,  $\text{MgCl}_2$ , and  $\text{MgSO}_4$  to flat granulating surfaces, using wet compresses. The results varied with the salt used, and the most marked differences were noted between the effects of NaCl and  $\text{CaCl}_2$ . NaCl caused the granulations to swell above the level of the surrounding skin.  $\text{CaCl}_2$  caused them to shrink even in a few hours till they became level with the skin. Wound secretion was not much influenced by NaCl; with  $\text{CaCl}_2$  it was diminished very markedly and became serous. Mg salts appeared to damage the tissues somewhat. Epithelialization was hindered by NaCl owing to hypergranulation, and promoted by  $\text{CaCl}_2$  indirectly, owing to the shrinking of the granulations. These opposite effects of Na and Ca are in keeping with what we know of their antagonistic effects in biology. Sodium loosens the colloid of protoplasm and makes the cell more permeable. Calcium has the opposite effect. From various experiments the anion is found to have little, if any, influence. The practical application of these data lies in the employment of NaCl solutions when we wish to stimulate granulation formation, to fill up deep wounds, and to use  $\text{CaCl}_2$  for flat granulating surfaces.  $\text{CaCl}_2$  is particularly useful in the case of burns.

63.

#### Studies in Local Immunity.

BESREDKA (*C. R. Soc. de Biologie*, June 2nd, 1923, p. 7) states that if an eighteen-day broth culture of staphylococci be filtered through a caudle a clear liquid is obtained which is devoid of toxicity for animals. In this liquid, though other microbes grow almost as readily as in fresh broth, the staphylococcus refuses to grow. This is due to the presence of an inhibitory substance, which can be shown to be thermostable and specific. If this liquid be injected into the skin of a guinea-pig—or, preferably, applied as a dressing to the shaved surface—it acts as a vaccine, enabling the animal to withstand a lethal dose of living cocci given the following day. The rapidity with which immunity appears would seem to exclude the action of antibodies and to indicate that it is in the skin itself that the resistance develops. Applying this idea of cuti-vaccination, A. Bass (*ibid.*, p. 9) has treated 25 cases of furunculosis, 5 cases of anthrax, 4 cases of acne, and 3 cases of pyorrhoea by the injection of killed cultures of the responsible microbe into the skin or mucous surface, as close to the lesion as possible. When dealing with staphylococci an autogenous vaccine was prepared, sensitized and killed by heat at 65° C. for forty minutes. Injections were given every two days. To cure boils four to six injections were required, to cure anthrax six to ten. Acne and pyorrhoea demanded a treatment of four to six weeks with a mixed staphylo-streptococcal vaccine. Many of the patients thus treated were seen after eighteen months to two years, and in none of them had a relapse occurred.

#### 64. The Relationship between Auto-haemotherapy and Haemoclastic Shock.

THE beneficial effect of auto-haemotherapy on patients suffering from furunculosis has been demonstrated by French workers. What is its mode of action? This is the question asked by NICOLAS, DUPASQUIER, and DUMOLLARD (*C. R. Soc. de Biologie*, May 26th, 1923, p. 1293). That it is not due to a process of vaccination is shown by the fact that the same result can be obtained by the injection of the blood of other human beings and of that of animals, such as the rabbit or guinea-pig. It was noticed that patients subjected to hetero-haemotherapy show pronounced general reactions, and it was therefore surmised that this shock might bear some relationship to haemoclastic shock. To ascertain if this were so, a patient suffering from chronic pruritus was submitted to auto-haemotherapy and a study made of the biological effects produced. It was found that after each of the four injections given there was a fall in the blood pressure, a decrease in the coagulation time of the blood, followed about half an hour later by a rise to above normal, and a definite leucopenia. From this it would appear that the effect of auto-haemotherapy is to cause a marked humoral disturbance similar to that encountered in haemoclastic shock.

#### 65. The Antagonistic Action of the Suprarenal Cortex and Medulla.

P. BRU (*Arch. des Mal. du Cœur des Vaisseaux et du Sang*, April, 1923, p. 256) observes that experiments in suprarenal physiology are rendered difficult by the complexity of these organs, formed of two substances absolutely distinct both embryologically and histologically. Moreover, the cortex and medulla penetrate each other reciprocally. Bru has succeeded in preparing emulsions of pure cortex and medulla of a dog's suprarenals. These emulsions were injected into the peritoneal cavities of rabbits. Each rabbit received three injections at intervals of eight or ten days. Eight days after the last injection 60 to 80 grams of blood were removed from the rabbits' carotids, and 10 c.cm. of rabbits' serum was injected into the saphenous veins of chloralized dogs. The effect was not immediate, but four or five minutes after injection of the "cortical" antiserum a definite fall of blood pressure occurred and persisted for more than fifteen minutes. An injection of 25 c.cm. of antiserum produced a more rapid and definite fall, with weakening and acceleration of the heart-beat. On the contrary, similar injections of "medullary" antiserum raised the blood pressure, in one case, from 17 to 19 cm. Hg in four minutes. Bru concludes that these antisera permit the dissociation of the two constituents of the suprarenal capsules, the cortex lowering blood pressure while the medulla raises it. This conclusion is confirmed very clearly by the successive injections of the two antisera at an interval of fifteen minutes (in the same animal). The pressure lowered by the "cortical" antiserum is raised to its former level by the injection of the "medullary" antiserum, while the pressure raised by the latter substance is lowered by an injection of "cortical" antiserum. Bru suggests that the "cortical" antiserum should prove valuable in combating certain syndromes of hypertension.

ANNUAL MEETING NOTES.

THE REPRESENTATIVE ALTERNATE.

THE main feature of the first day's debate in the Representative Body (reported fully in the *STANDARD*) was its simplicity and directness. There were no secure issues; there was no close voting; and there was no less strong feeling than might perhaps have been expected. Two matters stand out in Friday's proceedings: Dr. Gibbs's acknowledgment of co-operation between the British Medical Association and the Society of Medical Officers of Health. The course of the latter discussion was a little surprising, in view of the very strong position to the proposals shown by a section of the Council throughout the whole course of the negotiations with the Society. The meeting was prepared for full-dress debate, and so ready to applaud a good point in either side that the way the voting would go was first in doubt; but the large majority of representatives seemed to have decided beforehand that the object of the scheme was sound, that the scheme itself would attain that object, and that the time had come to adopt it without more ado. The opponents of the proposed policy failed to show the meeting any valid reasons for believing that it could not work; consequently their criticisms had little weight in influencing opinion, and there was almost a rout of unhealthily about some of the objections to "the public vote." The Representative Body had evidently travelled a long way since this subject was debated at the ambulance meeting, and personal or sectional animosity was refreshingly absent. Dr. Sanders, as a spokesman of the health officers, did nothing but good by his emphasis on the danger to the association of a separatist policy, and of the advantages that would flow to it under the proposed scheme. Mr. Turner, in summing up the whole history of the policy, dealt in facts and not compliments when he attributed the successful evolution of the scheme to the statesmanship of the Chairman of Council. After the scheme had been accepted by a very large majority in full house, the afternoon's work on the necessary modifications of Articles and By-laws was mainly formal. Notwithstanding an eleven-hour effort to defeat the scheme by constitutional procedure, the proposals of the Representative Body were mainly formal. The over-green question of providing individual medical reference was debated with considerable vigour. It may be doubted whether the Watlington motion would have been so had any of its supporters been able to indicate any practicable method of working such a scheme. The general feeling seemed to be one of regret that the British Medical Association should not be in a position to meet every conceivable need of every one of its members, from the time of qualification to the time of retirement.

Business on Saturday was again dispatched with unlooked-for celerity, the Representative Body rising before 3.30 p.m. after dealing with the Hospitals' Journal, Science, Public Health, and Ethical Committees' reports, and some outstanding matters on that of the Organization Committee. The second day's session was mainly occupied in debating the Hospitals and Insurance Acts Reports; discussion on other matters was limited to isolated points, and was for the most part simple and direct. The speech of the Chairman (Mr. Souttar) in presenting the Science Committee's report deserves special mention, as it introduced matter not covered by the printed report—notably the large number and very high quality of this year's applicants for scholarships and grants, and the prospect of increasing activity in post-graduate education. Dr. Macdonald's presentation of the Journal Committee's report was received with great cordiality. The absence of any prolonged discussion on medical ethics was in conspicuous contrast with the record for the last three years. The Public Health report was practically confined to a list of subjects dealt with; but the discussions under their head on tuberculosis, summer-time, and vaccination, more especially the last, should prove of value to the public. The course of debate on the motion for representation of the Medical Women's Federation on the Council of the Association seemed to be determined largely by the way in which the motion was worded. Not even Dr. Hawthorne's admirable and highly appreciated argument from analogy could do away with the facts put forward by the proposer as calling for action. The introduction of the Hospitals report completely changed the atmosphere of the meeting. It was evident that here, at least, there was sharp disagreement both on principles and on procedure. For the first time in three years a position apparently consolidated has been withdrawn from. Three elements could be detected in the several amendments on the agenda paper—criticism of the Hospitals Committee for its conduct of this matter, fear of an irretrievable split in the Association, and the objection (strongly felt by many influential consultants and others) to compromising "what might be called the 'high honours' position by accepting any payment not balanced as an honourarium. At Glasgow the Hospitals Committee was instructed to find the best method of bringing together two apparently irreconcilable views. The Portsmouth meeting has decided by a small majority that the method suggested does not suffice, and the problem therefore remains for solution next year. A guess may be hazarded that the decisive factor in the decision ultimately taken this year was fear of disruption of the Association, which outweighed the fact clearly enough put before the meeting by Mr. Souttar and by the Chairman of Council, that opportunity waits on no man, and those who do not lead must expect to be forced to follow. The debate was remarkable more for the diversity than for the novelty of the arguments brought forward. For the rest, the Bolton and Barmston representatives, ably assisted by Dr. Hawthorne, gave the meeting an interesting essay in definition, but in so doing they failed to accept Dr. Breckenbury's challenge to define "free will" as a preliminary to defining the adjective "voluntary." This may have been why Mr. Hayman's indication of his own working definition was accepted. The afternoon's discussion on the report of the Insurance Acts Committee was conducted with far greater reserve, presumably because the pressure of external circumstances was in this instance more urgent. The debate on Document M.10 traversed delicate ground. The meeting showed itself unwilling to compromise the position of the Insurance Acts Committee by unnecessary criticism at this stage of the negotiations. In the discussion on the schedules defining the range of medical service under the Acts, it was interesting to note the emphasis laid on the position of the Insurance Acts Committee as working primarily in the interests of the insured person. The debate left that Committee in at least as strong a position as it found it.

The morning session on Monday, July 23rd, was devoted to consideration of the finance report and the new home of the Association; the afternoon session to medico-political, parliamentary, and naval and military matters. Dr. Gordon Bell's attack on the financial statement was of service, if only as eliciting the independent defence offered by Dr. David Lawson and Dr. Peter Macdonald. Dr. Souttar) in presenting the Science Committee's report deserves special mention, as it introduced matter not covered by the printed report—notably the large number and very high quality of this year's applicants for scholarships and grants, and the prospect of increasing activity in post-graduate education. Dr. Macdonald's presentation of the Journal Committee's report was received with great cordiality. The absence of any prolonged discussion on medical ethics was in conspicuous contrast with the record for the last three years. The Public Health report was practically confined to a list of subjects dealt with; but the discussions under their head on tuberculosis, summer-time, and vaccination, more especially the last, should prove of value to the public. The course of debate on the motion for representation of the Medical Women's Federation on the Council of the Association seemed to be determined largely by the way in which the motion was worded. Not even Dr. Hawthorne's admirable and highly appreciated argument from analogy could do away with the facts put forward by the proposer as calling for action. The introduction of the Hospitals report completely changed the atmosphere of the meeting. It was evident that here, at least, there was sharp disagreement both on principles and on procedure. For the first time in three years a position apparently consolidated has been withdrawn from. Three elements could be detected in the several amendments on the agenda paper—criticism of the Hospitals Committee for its conduct of this matter, fear of an irretrievable split in the Association, and the objection (strongly felt by many influential consultants and others) to compromising "what might be called the 'high honours' position by accepting any payment not balanced as an honourarium. At Glasgow the Hospitals Committee was instructed to find the best method of bringing together two apparently irreconcilable views. The Portsmouth meeting has decided by a small majority that the method suggested does not suffice, and the problem therefore remains for solution next year. A guess may be hazarded that the decisive factor in the decision ultimately taken this year was fear of disruption of the Association, which outweighed the fact clearly enough put before the meeting by Mr. Souttar and by the Chairman of Council, that opportunity waits on no man, and those who do not lead must expect to be forced to follow. The debate was remarkable more for the diversity than for the novelty of the arguments brought forward. For the rest, the Bolton and Barmston representatives, ably assisted by Dr. Hawthorne, gave the meeting an interesting essay in definition, but in so doing they failed to accept Dr. Breckenbury's challenge to define "free will" as a preliminary to defining the adjective "voluntary." This may have been why Mr. Hayman's indication of his own working definition was accepted. The afternoon's discussion on the report of the Insurance Acts Committee was conducted with far greater reserve, presumably because the pressure of external circumstances was in this instance more urgent. The debate on Document M.10 traversed delicate ground. The meeting showed itself unwilling to compromise the position of the Insurance Acts Committee by unnecessary criticism at this stage of the negotiations. The debate left that Committee in at least as strong a position as it found it.

# The Ambulatory Treatment of Fractures and Diseased Joints

By CAREL A. HOEFFTKE

7, HARLEY STREET, W.1.

(Inventor and Maker of Hoefftke's Appliances.)

WITH AN INTRODUCTION BY

FRANK ROMER, M.R.C.S., L.R.C.P.

AND ARTICLES BY MANY EMINENT SURGEONS AND PHYSICIANS.

Royal 8vo.

Price 17s. 6d. net.

THE publication of Mr. Hoefftke's book describing the ambulatory treatment of fractures and diseased joints with his extension appliance and giving cases and results, is a timely reminder of the existence of an apparatus for the application of a principle far too little known or appreciated. Hitherto descriptions of this treatment and testimony as to its value have been confined to papers read before the Medical Societies, articles in Medical Journals and short descriptions in Medical Books. The publication of this amply illustrated work, demonstrating its application to disease and fractures, should be the means of bring home to the Profession the extent of the mitigation of suffering obtainable by the use of the principle involved in this unique extension appliance. It is invaluable not only for fractures of the long bones of the lower extremities, but also because the whole field of arthritic pathology comes within its scope. A permanent cure may be confidently expected to follow its use, and not merely amelioration of the condition.

The mode of manipulation of tubercular and arthritic joints and their extension on Mr. Hoefftke's extension table, by means of which the danger of friction between the articulating surfaces during the operation is avoided, is described in detail. Many distinguished medical men have altered their views upon the treatment of fractures and diseased joints, thus:—

Sir Arbuthnot Lane, Bart. (Consulting Surgeon to Guy's Hospital), writing in the *Lancet* of May 29th, 1920, says: "Quite a number of years have elapsed since my views on the treatment of tuberculous, rheumatoid, and other conditions of joints by means of rest were first shaken and then altered by the observation of the results of the combination of movements and extension afforded by Mr. Hoefftke's appliances. Up to that time I was imbued with the view then accepted, that rest was a factor of vital importance in the treatment of diseased joints. I then learnt that if sufficient extension could be exerted to take pressure off the opposing articular surfaces of the affected joint, movement was most beneficial and often accompanied by little or no pain. . . . The advantages afforded by the forcible separation of the diseased articular surfaces from one another, combined with free movement, are best shown by the use of a really efficient extension apparatus for the leg which does not interfere with the functioning of the diseased joint. This is effected by the apparatus which Mr. Hoefftke has devised. . . ."

The cases quoted throughout the book, illustrated by X-ray photographs taken at intervals, have been sent to Mr. Hoefftke by medical men, who all bear testimony to the efficacy of the ambulatory treatment.

It is evident that the severity of traumatism, the duration of the disease, and even the age of the individual are factors which may be disregarded when ambulatory extension treatment has been decided upon. Tuberculous joints in children, rheumatoid arthritis with ankylosis in the aged, contractions with suppurating sinuses due to bony injuries, compound fractures, are all amenable to treatment by means of the Hoefftke extension method, even after years of neglect or when other means have failed to effect a cure.

The principle of the treatment with Hoefftke's appliance is *Extension with Movement*, transferring the weight of the body to the tuberosity of the ischium and surrounding gluteal muscles, leaving the pubic bone and perineum quite free from pressure. By means of a well-fitting ankle-spat powerful extension up to 25 lbs. can be produced night and day upon the joint surfaces without discomfort to the patient. With the help of this appliance the patient can be allowed to walk about and exercise the joint, so as to avoid slowing the blood supply, and to enable the usual blood current to combat the disease and repair the cartilage and articulating surfaces. Enough has been said to indicate the physiological principles of this treatment and the scientific aim of the extension appliance.

If this book be studied in an unbiassed spirit the Publishers are convinced that they will have placed in the hands of the Profession the means to an invaluable addition to surgical and medical therapeutics.

THE UNITED  
MEDICAL JOURNAL  
153

A new and very welcome feature was introduced into the early part of the Annual Meeting this year. Before the Representative Body concluded its sessions the delegates from Overseas Branches were entertained to luncheon at the Corner House, Portsmouth, under the chairmanship of Dr. Wallace Henry, Chairman of Representative Meetings. Those present on Tuesday, July 24th, to welcome them on this informal occasion included the principal officers of the Association, the Chairman of several Committees, and the chief officials. The guests represented widely scattered parts of the Empire—India, Australia, New Zealand, South Africa, West Indies, Malaya, Zanzibar, Sierra Leone, and Hong Kong. Their names are: Sir Joseph Vero (South Australia); Major-General Sir G. Godfrey Giffard (South India and Madras); Dr. E. P. Baumann (Witwatersrand); Dr. B. Speckman (Zanzibar); Dr. W. J. Owen-Pritchard (Tanganyika); Dr. Beninger (Sierra Leone).

On Sunday, July 22nd, when the Representative Body rested from its labours of the two previous days, a large party of representatives and ladies accompanying them made a most enjoyable trip by sea to Southampton. The party left the Clarence Pier, Southsea, on the steamer *Duchess of Fife* at 10 o'clock, in delightful weather. Making its way past the island forts of Spithead and the anchored aircraft carrier H.M.S. *Argus*, the boat steamed towards Ryde and then passed along the wooded shores of the Isle of Wight to Cowes Harbour, before turning into Southampton Water. Bright sunshine and a cool breeze, and glimpses of the white sails of racing yachts in the Solent, contributed to the pleasure of the voyage. As Southampton was approached, and the long facade of Netley Hospital came into view, the vast funnels of ocean-going liners could be seen towering above the quays and dwarfing the cargo boats moored in the estuary. Disembarking at the Harve Dock, a visit was paid to the cross-channel packet-boat *Normannic*, after which the party was entertained to luncheon at the South-Western Hotel by their hosts for the day, the Southampton Division of the British Medical Association. The visitors then walked to the White Star liner *Messiah*, which was lying at her berth beside one of the longer quays, and every part of this luxurious great ship was inspected by kind permission of the directors of the White Star Line.

here, when the country becomes alive, as it eventually must become alive, to the social and hygienic necessity as well as to the economic advantage of clearing the foul slum areas that disgrace the life of our great industrial centres, and breed and perpetuate an underworld, both moral and physical, whose end-results we annually spend millions of the taxpayers' and ratepayers' money in attempting to alleviate—it is here that the wage-earning classes of Portsmouth should find a sure escape from the poisonous, sunless, and depressing conditions in the slums of Portsea.

Next one word about the most famous of all our ships—H.M.S. *Victory*. She was not built at Portsmouth, though she had been the town's most treasured possession ever since she returned here, more than a century ago, with the dead body of a nation's hero. For over one hundred years she floated at the mouth of the harbour, the sentinel of England's greatest naval port, and the token of perhaps her most glorious days. Quite recently, as you are aware, owing to the ravages of time she has had to be removed to the dockyard, where no doubt many of you will be visiting her during the week. It is a national, no less than a local, satisfaction to know that owing to the energetic effort of Admiral Sir Doveton Sturdee and the ready response to his appeal, she will be restored to a condition worthy to fly the flag of the Commander-in-Chief of the first naval port of the Empire.

Portsmouth's past is writ large in the annals of our history. It is a town whose walls and stones, if they broke silence, could almost tell the story of the great empire over which the Union Jack flies. It is less easy to forecast its future. It has leant in the past on the British Navy, and the British Navy has leant no less upon it. All its interests have been sacrificed to the needs of a nation. It is not denied that this has had compensating advantages for the town. It would seem, however, if its energies are no longer to be required for small purposes, to be only fair that every consideration and every facility should be given it by the Government during the transition period which must elapse before it can make good in other directions and stand firmly upon its feet again. With these few remarks regarding local topics, I pass on to the subject of my address.

### ENVIRONMENT AND HEALTH.

During the past fifty years medicine has done infinitely more to constitute itself a science than in all the previous ages. This has been mainly due to the flood of light thrown upon the specific etiology of many diseases by the epoch-making discoveries of Pasteur, and the stimulus those discoveries have given to other workers. Previous to this almost nothing was known of the agencies concerned in the onset of any diseases, except those of purely mechanical origin. Of such widespread and prevalent disorders as the surgical infections, enteric fever, tuberculosis, diphtheria, syphilis, malarial fever, pneumonia, and many others, the causes were entirely unknown, the speculations and theories as to their origins were various—"Quot homines, tot sententiae"—and their treatment was entirely empirical. All disease was a mystery. A great deal of it is no longer a mystery. Approximately one-half of the diseases with which we are acquainted are now known to have their origin in infection by living organisms belonging either to the plant or to the animal kingdom, and the probability is that the list is not yet nearly exhausted. Besides this it has been computed that nearly half the deaths that occur annually are traceable to the same cause.

With the emergence of medicine from the mysterious, no less a revolution has occurred in the practitioner of medicine. While a good bedside manner is still a valuable asset and will so remain in so far as it connotes a sympathetic and human attitude towards the sick and suffering, and while from a business point of view a good shop front no doubt has its value, no longer are the doctor's brains assessed by the sheen of his tall hat or the length of his frock-coat. Like medicine, the doctor has become less mysterious, less aloof from and superior to his fellow men.

Knowing more he has become less omniscient. Standing on surer ground he has become less pretentious. The medical priesthood, reminiscent of a time when the medicine man was more priest than physician and more charlatan than either, has disappeared or is disappearing. This is all to the good, and tends to a more enlightened confidence between doctor and patient.

Again, so much relating to the discoveries and advances in medicine nowadays finds its way into the lay press that the general public has, apart from its technical aspects, a broad knowledge of the progress medicine is making, and is alive to its new developments. This is again to the good. A strong opposition is always an incentive to good government. The advent of a wide-awake and informed public tends to keep the profession up to the mark. It adds nothing to the dignity, not to mention the security, of the doctor to be questioned by his patient on some new treatment or phase of a disease he has never heard of, but with which he finds his patient has more than a bowing acquaintance.

It was a natural sequence of the elucidation of the causative agent in many of the infectious diseases that scientific effort should be directed to two main objectives: first, to the discovery of means of producing an artificial immunity similar to the active natural immunity which it was a matter of common knowledge resulted after recovery from an attack of many of them; secondly, to producing immunity reactions which should have the effect of neutralizing the toxic products of the invading organisms during an attack. In both of these directions remarkable results have been achieved, both by what is known as vaccine prophylaxis and therapy, and antiserum prophylaxis and therapy.

The most completely successful example of vaccine prophylaxis is that of vaccination against small-pox, introduced by Jenner in 1798. This remarkable discovery was the result of shrewd observation and logical deduction. It was nevertheless empirical; the principle on which it rested was not understood until the work of Pasteur more than half a century later. In countries where vaccination is twice practised, small-pox has practically ceased to exist, and its sporadic outbreak from time to time is a warning to the public of neglect of the means to prevent it. In typhoid and paratyphoid fever, by measures along the same lines, immunity lasting for a period of one or two years can be secured, and has greatly reduced the incidence of these diseases both among civilians and soldiers.

Again, the mortality from rabies has been reduced from 16 per cent. to a fraction of 1 per cent., an active immunity being capable of being produced here after infection has already taken place, owing to the lengthy incubation period of the disease. Vaccine therapy—that is, the production of active immunity after attack by a known micro-organism—so ably advocated by our own countryman Sir Almroth Wright, has given very beneficial results in staphylococcus infections, skin affections, etc. Of antiserum prophylaxis the best example is that obtained in tetanus. The mortality following Fourth of July injuries in America has ceased to exist owing to its use, and no less life-saving results were obtained by the same means in the great war. The most familiar and the most successful instance of antiserum therapy is that of diphtheria, which has reduced the mortality from 40 to 10 per cent., and, if used on the first day of the disease, to almost nil.

These are veritable triumphs of strictly scientific medicine. In other diseases more or less success has been achieved. But closer investigation has shown that there are many factors requiring elucidation which undoubtedly influence the result—such as choice of route, recognition of different types of the same disease, etc.—and it will certainly take many years of patient endeavour before the ultimate possible results in securing immunity are obtained. In many instances prophylaxis or cure has eluded us, and the results have proved disappointing. The above may be termed the result of scientific effort, either preventive or curative, directed towards the individual.

There are other diseases, which have been attacked from a totally different angle—namely, by studying and combat-

The industrialization of Sweden since 1870 has been accompanied by a high adolescent mortality due to pulmonary tuberculosis. Sandberg, commenting on this, says:

"The cause of this difference between earlier and more recent times seems to us to be in the fact that formerly the adolescent boy and girl remained at home for a longer time—nowadays one goes more frequently and at an earlier age to the city or factory. The new conditions of existence bring, in many cases, increased dangers to health and life, dangers which, especially in the case of women, often lead to tuberculosis."

In 1885 the tuberculous gland cases admitted to the Alexandra Hospital for Sick Children, Brighton, constituted 6.5 per cent. of all admissions. In 1899 they were 3.5 per cent.—a reduction of nearly 50 per cent. Between 1885 and 1899 Brighton has swept away most of its insanitary areas. Numbers of similar instances could be quoted. It is no unwarrantable assumption that by permitting—and that is all we have to do—the sun and fresh air into our slum areas we should see a very marked general decline in the incidence of tuberculosis.

Consider next Rickets. Its etiology is unknown. There are two opposing theories as to its origin—the dietetic and the hygienic. There are those who positively assert that it is a deficiency disease; that it is due mainly to lack of fat-soluble A. There are others who as stoutly deny that diet has anything to do with it. We may leave the theorists to settle their differences and turn our attention to certain facts about it which have long been established, and certain other facts which have recently come to light. It never occurs among races living under natural conditions, and is especially prevalent among the poor in Europe and America living under so-called civilized industrial conditions—in other words, the thoroughly bad hygienic conditions of overcrowding and absence of fresh air and sunlight. Among the well-to-do it is practically unknown. In India, on the other hand, as recently shown by Hutchinson, it is a disease of the rich. It does not occur among the poor labouring class who live an open-air life, but is prevalent among the rich Mohammedans and Hindus, who are confined in airless and sunless rooms. Hutchinson discovered also this remarkable fact—that late rickets was restricted to females, who alone are confined, according to the purdah system of isolation as practised by the wealthy natives of India. Again, eminent observers in Glasgow, who have quite an exceptional acquaintance with rickets—it being, as you know, very prevalent in that city—have always associated the disease with overcrowding and lack of hygienic conditions and sunshine, which you also know are conspicuous features of that great hive of industry. According to Miss Fergusson, 50 per cent. of the children in the poor quarters of Glasgow are rickety—a vastly smaller proportion in garden cities, such as Bournville. The prevalence of rickets, she says, is associated with close confinement in tenements. Most important of all, we have the recent experiments of the Lister Institute in Vienna. They prove conclusively that a deficient diet can only produce rickets in the absence of sunlight. If abundant sunlight be present a deficient diet is powerless to give rise to it. Lastly, we have the significant fact that the sun's rays without any other treatment whatever can cure it—an explanation of the oft-repeated dictum that anybody can cure rickets in the summer.

All this does not prove that the absence of fresh air and sunlight is the cause of rickets; but it does prove this—that in overcrowding, confinement, want of fresh air and sunlight, we have an environment conducive to the development of rickets, either by the supply of conditions favourable to the activities of the virus, whether microbic or otherwise, or by lowering natural resistance to it. Conversely, that fresh air and sunlight and good hygienic conditions furnish an environment which is powerfully antagonistic to the disease; that they have either the power of damping down the activities of the virus whatever it is, or that they can so alter the metabolism of the body as to provide an increased resistance and immunity to it. Whichever is the method, the result is the same. These facts appear to indicate clearly and unmistakably the way to the control of this crippling and dangerous disease. And, as Mellanby says, its eradication would do away with a great deal of the bone deformity, improve the physique, lower the infantile mor-

talidity, and, most important of all, improve the teeth of the people of this country beyond recognition.

Let me invite your attention in the next place to Venereal Diseases, which have figured so largely in the public eye during recent years, are discussed in every drawing-room, exhibited at every picture house, and with regard to the most suitable methods of controlling which there are acute differences of opinion, both among medical men and the lay public. They are the diseases of immorality. The contributing environmental factor here is the indiscriminate admixture of the sexes of all ages, a necessity of their living conditions. It is not, of course, contended that by an improvement in housing immorality would be stamped out, but it is contended that the conditions of overcrowding, without regard to age or sex, which exist in our industrial centres make the practice of morality well-nigh impossible.

Let me put before you a few facts; they are taken from the report of Dr. Chalmers, the medical officer of health for Glasgow, for 1921. There is no intention to single out that city as a sink of iniquity, or an example of a condition of things peculiarly revolting to the conscience of civilized humanity, and I have very little doubt its case could be paralleled in our own borough of Portsmouth; but I have the facts for Glasgow, and I have not similar facts for Portsmouth. In Glasgow, out of a population exceeding a million, over 600,000 live in one-roomed or two-roomed tenements. Under the heading "Sex overcrowding in small houses," Dr. Chalmers gives the following appalling examples:

"In a one-roomed house a father of 52 occupied the same bed with a mentally defective daughter of 24, who had an illegitimate child of 10. In another, with space for five adults, a father and daughter shared the same bed. In another a mother shared the same bed with two sons of 19 and 20 years respectively. In two-roomed houses, in one instance, a son of 19 and a daughter of 21 occupied the same bed; and in another a son of 19 and a daughter of 25, who was pregnant."

However revolting these facts may be, it is right that the public should be made aware of them. This, then, being an example of the state of affairs in our industrial centres, it may be confidently stated that a great deal, at all events, of immorality and its consequences, venereal disease, is the direct result of environment—that the conditions existing make either the teaching or practice of morality impossible, and furnish the breeding ground for venereal disease.

Have we not, it may be asked, missed one phase of the problem, and are we not somewhat out of touch with the situation, with our societies for the prevention of venereal disease and for combating venereal disease quarrelling amongst themselves as to the best means of meeting the evil, and local authorities and the lay public equally divided, when conditions such as I have depicted are rampant in our midst? It is this aspect of the problem—the immorality and its consequence, venereal disease, which are the direct result of overcrowding without regard to age or sex—which I wish to lay particular stress upon here.

Consider, lastly, the abuse of alcohol. There is no doubt that, without anything in the nature of prohibition in this country (and I believe it to be foreign to the instincts of our people to have their lives, what they may eat, and what they may drink, regulated by the policeman), there has taken place during the past fifty years a steady move in the direction of greater sobriety among all classes of the community. Among the upper and middle classes drunkenness was the fashion less than a century ago. It is now a disgrace. In the army, navy, and mercantile marine there was, fifty years ago, infinitely more drinking than there is to-day. In the streets of our towns the drunken man of any class is not nearly such a familiar sight as he was a generation ago. This must be attributed broadly to social evolution, to general civilizing influences—better education and the inculcation of greater self-respect, which such influences promote. There are, of course, many factors at work here; but in the forefront of civilizing influences is the improvement of the home. So long as the public-house is more comfortable and more attractive than a man's home, the former will claim his leisure hours. Give him a comfortable and respectable home, and the lure of the public-house will automatically diminish. In the debate on Lady Astor's bill, a few months

The bill was read a second time.

Dr. Russell has obtained a second rat sarcoma in the preparatory work for the present study. He has already given one as described in his paper on the series which has already been published last year. It arose after an interval of six months from the last rat injection and eighteen months after the beginning of the experiment. He has continued his investigations on the utilization of carbohydrates by sarcoma-bearing tumor cells, extending them to a study of the pentoses. Some of them are apparently more easily attacked by cancer cells than others are. He is also continuing his work on the law generally for dealing with these matters.

of normal tissues. The indications and/or experiments will be the basis of chemotherapeutic experiments in which he will have the collaboration of Mr. H. G. Crabtree, M.Sc., who has joined the scientific staff for this purpose.

Mr. Flanagan asked whether the Minister of Health would consider the advisability of supplying Government staff with all private qualified medical practitioners who applied for it, as the Government now have to use might not be up to this method of Government standard. Mr. Chamberlain said that this matter had been considered from time to time, but he did not decide whether it was practicable to take action in the direction indicated.

Replying to Mr. Bennett on July 18th, Mr. Chamberlain explained that the arrangements governing the appointment of medical officers were made solely with a view to securing a high standard of efficiency.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

## Medical Notes in Parliament.

*Restriction of Sale of Alcohol to Young Persons.*  
In the House of Lords, on July 19th, Lord Dawson of Penn spoke for the second reading of the bill already referred to. He said that the measure he had heard one word of grudgingly, but a large proportion of the people for any class whatever, would support it. He said he should have been more happy if he had heard one word of grudging, but a large proportion of the people for any class whatever, would support it. He said he should have been more happy if he had heard one word of grudging, but a large proportion of the people for any class whatever, would support it. He said he should have been more happy if he had heard one word of grudging, but a large proportion of the people for any class whatever, would support it.

[illegible][illegible][illegible]

However, the community is a large and diverse group, and the health care system is not always able to meet the needs of all. The health care system is not always able to meet the needs of all. The health care system is not always able to meet the needs of all.

The following table shows the number of patients treated at the hospital in 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579

was doing no more than was done in many other aspects of social behavior. After all, to limit alcohol in adolescence and to limit the use of discipline in the home are made selective decisions. There are no good reasons for restricting calling or specializing in medical knowledge and training. At headquarters we were not employed on administrative work, we were advising medically upon cases presenting special difficulty.

in the dark sunless and airless environment of our large towns are inviting both all the time. The most important educational requirement of domestic hygiene and its highest fulfilment is the open window, night and day, summer and winter. It is astonishing how quickly the human organism abjures the hothouse conditions of civilized living and adapts itself to its natural environment, fresh air. The tuberculous patient, after three months' open-air treatment in a sanatorium, cannot endure the closed window in his own home. The tuberculous children at Loysin in Switzerland, and at Alton and Hayling Island in this country, live practically naked in the open air, and by that habit and that habit alone throw off a most formidable and deadly disease. Why, then, all the care of healthy children, with their active metabolism capable of adapting itself to almost any requirement, to wrap them up in the warmest of clothing, confine them in hot rooms with windows shut, keep overy draught from their bodies, and submit them to general hothouse conditions suitable only to the old whose metabolism is barely sufficient to keep body and soul together, and whose clock has almost run down?

Modern civilization is suffocating itself in the polluted atmosphere and darkness of our great industrial cities. The need of pure air and sunlight, of which there is plenty about, and to be had for nothing, was never so insistent as it is to-day. These great gifts of nature were plentifully supplied to primitive man, and were his only sure defence against disease. They are as bountifully given to civilized man, but he seems to have lost sight of their value, or to have deliberately turned his back on them, while he requires a whole volume for the mere nomenclature of his innumerable diseases.

Perhaps apology is needed for touching to-night on a problem which may be considered rather a sociological one than one of strictly scientific medicine. But apart from the fact that I believe a wide latitude is permitted in the Presidential Address to this Association, my choice of subject can, I think, be justified by both local and general as well as scientific considerations. First of all, it does not seem to be an unfitting subject to bring to your notice in the town which bred Charles Dickens and Walter Besant, who devoted their unrivalled literary talents to depicting scenes and characters drawn from our slums, and such as our slums are only too familiar with. Secondly, although this borough has witnessed some of the most brilliant pageants and displays in the history of this country, and although you are sitting here in what we are proud to think is one of the finest town halls in the kingdom, yet there is an obverse to the shield, and round the corner we can introduce you to slums as pestilential and overcrowded as any to be found in the land. Further, although the environment of the wage-earning classes, in our industrial centres, and its effects may in part be a sociological question, I have endeavoured to show that it is inseparably linked up with, and is in fact the greatest of all our problems of preventive medicine, the most rational and the most scientific of all medicine. And if this is so, then it is up to the medical profession, both individually and through this great Association of medical men, to educate and lead public opinion in this matter, and to strengthen the hands of governments and local authorities, on whom will ultimately devolve the responsibility, no less than the odium, of providing the remedy. Concentration on the prevention of disease, on strengthening resistance to disease, by the improvement of environment, rather than on the search for cures or palliatives when the damage is already done; more attention to stimulating and fortifying the natural defensive mechanisms against disease, less to direct attack on disease itself; as Professor Wynne so ably put it last year, concentration on the environment rather than on the individual—this appears to me to be the most scientific, the most economical, and the most productive means of combating the worst of the evils from which the community suffers. If, in conclusion, I might sound a personal note, it is this—that as Chairman of the Health and Housing Committee of this great borough, by the goodwill of my colleagues on the Council, this is a conclusion forced upon me by no mere theoretical considerations, but by an everyday acquaintance with undeniable facts.

## British Medical Association.

**REPORT ON WORK OF SCHOLARS AND GRANTEES.**  
The following is an account of the results of work done by the Research Scholars and Grantees of the Association during the year 1922-1923 and reported to the Science Committee at its meeting on July 3rd.

### SCHOLARSHIPS.

Dr. H. A. HARRIS (Ernest Hart Memorial Scholar) has made a detailed study of a foetus presenting a combination of anomalies. In addition to numerous anomalies in the skeleton, the left lung and pleural cavity were absent, the oesophagus was interrupted at the level of the seventh cervical vertebra, and in place of the left bronchus was a narrow canal continued into the distal part of the oesophagus. From the left ventricle there arose a right systemic arch giving off the left carotid, right carotid, and right subclavian arteries. From the right ventricle ascended a left systemic trunk, giving off a right pulmonary artery and continuing as a left arch to join that of the right side, after giving off the left vertebral and subclavian arteries. A small communicating vessel united the ascending portions of the two arches. A full account is given in the *Journal of Anatomy*, vol. 57, 1922.

Dr. Harris has also examined three anencephalic foetuses; in all both the pituitary body and the intermediate zone of the suprarenal cortex were well developed. He has investigated the effects of disease on bone growth. In the case of a patient who had two severe illnesses at an interval of eight months, the alteration in the structure of the bones, as shown by radiograms, demonstrated clearly the amount of growth during that interval. From an examination of children and animals Dr. Harris concludes that (1) enlargement of the ends of the long bones is, within wide limits, normal; (2) the degree of enlargement is in some diseases greater than in rickets; (3) in many cases heading of the ribs may be confined almost entirely to the deep surface; (4) the "rickety rosary" and "cranio-tabes" are of less value than the radiogram in diagnosing the disease.

Dr. R. ST. A. HEATHCOTE (Research Scholar) has studied the action of camphor, menthol, and thymol on the circulation. The action of these drugs on the isolated perfused heart was found to be, in every experiment, purely depressant; both rate and amplitude of beat were reduced, the effect being due probably to direct action on the cardiac muscle. The action of camphor on the chloralized heart was also studied. After a short perfusion with chloral the heart beat became slower and the amplitude less. On changing to the mixture of camphor and chloral there occurred a rapid decrease in amplitude and rate, and no sign of stimulation of the chloralized heart was ever seen. The coronary flow was increased by all three drugs. Experiments on the circulation were performed on decerebrated cats, a solution of camphor in olive oil being injected subcutaneously or intravenously; a gradual fall in blood pressure was produced. From these experiments it was concluded that camphor possesses no value as a cardiac or circulatory stimulant.

Dr. Heathcote has also studied the active substances in squill. He has separated three substances—a glucoside fraction, a resin, and a third body, of unknown constitution but probably a derivative of the glucoside. The first resembled closely the glucosides prepared from digitalis and strophanthus in all respects. The resin was found to depress the rate of the heart and also to dilate the vessels, both coronary and systemic. The third body resembled in its actions the glucoside, but had only about one-third of its activity.

Dr. S. W. F. UNDERHILL (Research Scholar) has investigated the influence of the hydrogen-ion concentration of the environment upon the activity of smooth muscle (isolated ileum of the rabbit or cat). In the ileum it was found that a sudden alteration to the acid side of neutrality caused a diminution of tone with a decrease in the contractions, while a corresponding sudden change to the alkaline side caused an increase in tone with a less

## INTERNATIONAL PHYSIOLOGICAL CONGRESS.

## MEETING IN EDINBURGH.

THE eleventh International Physiological Congress is being held in Edinburgh this week under the presidency of Professor Sir EDWARD SHARPEY SCHAFER, who was in the chair at the first General Session on July 24th. Captain WALTER E. ELLIOT, M.B., Ch.B., M.P., Under Secretary for Health for Scotland, on behalf of the Government extended a cordial welcome to those attending the Congress and especially to those members who had come from distant places. He was followed by Sir THOMAS HUTCHISON, Bt., Lord Provost of Edinburgh, who welcomed the Congress on behalf of the City; the Congress, he said, was remarkable in that those attending represented no fewer than twenty-one different countries. Principal Sir ALFRED J. EWING, K.C.B., then welcomed the Congress on behalf of the University of Edinburgh; he mentioned the fact that the University had possessed a Chair of Physiology for two hundred years.

*President's Address.*

THE PRESIDENT (Sir Edward Sharpey Schafer) said that the several speeches of welcome had become progressively more intimate; beginning with the country at large, passing to the City of Edinburgh, and ending with the University. It was now his pleasant duty to tender the most intimate welcome of all, that of British physiology. Pointing to a bust of William Harvey, he said that the members of the Congress were invited to accept as a memento of the occasion a medal designed from that bust, a counterfeit presentment of the greatest of all British physiologists. The sculptor, Mr. Pilkington Jackson, was to be congratulated on his success; it had been necessary for him first to model a bust from authentic portraits of Harvey in order to obtain such an aspect of the subject as was demanded for the execution of a medal. "It is," the President continued,

"a far cry from Harvey to Lister, and many names eminent in British physiology intervene, but I desire especially to associate the name of Lister with this gathering, partly because he was for several years professor of surgery in this University, but chiefly on account of the fact that the researches which preceded his great discovery were researches in pure physiology, and were inspired by that great teacher William Sharpey, who migrated in 1836 from Edinburgh to London, and to whom I myself and many other British physiologists owe directly or indirectly their introduction to our science. Incidentally, it will be of interest to you to know that both Harvey and Sharpey were born in the same town—Folkestone—although at an interval of more than two hundred years. The countrymen of Harvey and Sharpey and Lister tender a cordial welcome to the countrymen of Vesalius and Van Helmont, of Magendie, Claude Bernard, and Pasteur, of Sylvius, Boerhaave, and Donders, of Caesalpinus, Fabricius, and Malpighi, of Michael Servetus, and of Albrecht von Haller, to mention but a few of the great names which are associated with our science."

The President then mentioned the names of physiologists who had died since the last meeting of the Congress, and concluded by saying that it was fortunate for the president of a Physiological Congress that he was not expected to give an account of the progress of the science since the preceding meeting. The task would indeed be difficult in view of the complexity of the science and the small part of it any one person could be expected to master. In view of the interest lately aroused and still existing, not only among physiologists but and even the general public, in the but o pancreas, a subject especially connected with the activities of the Toronto school, Dr. Macleod, the distinguished professor of physiology in the University of Toronto, had been invited to give a lecture on insulin.

INTERNATIONAL CONGRESS OF  
SURGERY.

(Continued from page 121.)

## ARTHROPLASTY.

THE discussion of the International Congress of Surgeons on Wednesday morning, July 18th, dealt with the subject of arthroplasty. All the speakers were good, but the masterly speech, cinema display, and exhibition of cases by Dr. Putti of Bologna earned him a personal triumph.

Mr. E. W. HEX GROVES (Bristol) said that arthroplasty should be defined as an operative procedure upon an ankylosed joint which had the object of restoring mobility. The pseudo-arthritis which sometimes resulted from a simple fracture proved that a new joint could be formed, including interarticulating ends of bone, capsule, and synovia, without any elaborate plastic operation under the influence of constant movement. But such a joint was unstable and always developed the features of osteo-arthritis.

Clinical evidence on the question of arthroplasty had accumulated slowly since, ten years ago, Murphy had described his methods of operative mobilization on hip- and knee-joints. It was still conflicting. There had been many disappointments. The operation upon the hip, the one usually tried, was very serious and had a high mortality. Those recovering had only a very limited movement and the functional result tended to get worse with the lapse of time. New hope had been felt with regard to these mobilizing operations since the publications of Professor Putti had been considered. Arthroplasty could never create a normal joint, and the average result was a gain in mobility at the expense of strength and precision. In any given case the question was, Will the abnormal joint produced by the arthroplasty be more serviceable than the stiff limb which it is proposed to treat? The answer must be considered under three headings: The nature of the causative disease; the nature of the disability; and the circumstances of the patient.

With regard to the causative disease ankylosis resulting from trauma, pyaemia, or gonorrhoea in which infection was at an end gave the best results from arthroplasty. In such a disease as tuberculosis the majority of joints were unsuitable for the operation because of the latency of infection and the deep involvement of the bone ends, but in exceptional cases where the disease had been almost confined to the synovial membranes and the bones were formed and dense a good result might be expected. Selected cases of osteo-arthritis and rheumatoid arthritis might give a considerable measure of success. If ankylosis had taken place in good position and was bony and painless the joint should be left alone unless mobility would make it possible for the patient to carry out his occupation. But if the ankylosis was in a bad position, was painful, or the deformity progressive, choice had to be made between operative fixation and mobilization. Associated ankylosis of hip and knee on the same leg demanded mobilization of the hip, whilst ankylosis of both knees required arthroplasty on at least one of the joints. It was still the opinion in this country that bony ankylosis of the knee in good position should not be interfered with unless present on both sides. Youth was entirely favourable to arthroplasty provided that growth of bones had ceased.

There were six essentials in the operations. These were: To make a sufficient gap between the bone ends; to shape the articular ends and to cover them; to provide synovial fluid; to provide ligaments and prevent undue mobility; and to restore function.

Enough bone must be taken away at the time of the operation to allow full movement desired, but no more. It was wise to trust to other measures to prevent refixation. All possible fibrous tissue, and especially that of inflammatory origin, must be taken away from the site of the new joint. In shaping the bone ends the greatest possible width must be preserved in the articular surfaces. Instead of leaving the bone raw the cut surfaces might be rubbed with hard wax—a simple procedure, but not so efficacious as the use of tissue flaps. These flaps might be a foreign membrane, free fascia from the patient's own tissue, or pedicle flaps of fascia, muscle, and fat. Fascia lata was perhaps best, but all that it could do would be to provide a smooth covering

bacteriological methods and a proficient technique in chemical procedures. So that apart altogether from the large number of undergraduate training, there must be a grounding in the methods.

I suggest that it is lack of adequate financial return for increased skill in technique that hinders the general practitioner. In an ordinary middle-class practice the patient at the present day is unable to meet fees additional to the usual charges for consultations and visits. As regards the insured person, little or no provision is made for payment in respect of additional services such as blood sugar estimations, and absolutely no encouragement given to perform such additional services.

Perhaps as we are medical men, we should do all this in a spirit of altruism. New methods, however, mean new apparatus, and perhaps little alterations here and there in the consulting room—in fact, more financial outlay. In the present state of affairs as regards the general practitioner—who increases his capital outlay is, perhaps, a bold man.

—I am, etc.,

London, S.W., July 17th.

W. HERBERT BIRCHER, M.D., J.D.

Sir,—I am an old Edinburgh medical student, and in the summer of 1888 I was chloroform clerk in the Royal Infirmary for six months. How we used to waste the chloroform! but I do not remember a single death in the five years I was there.

Our procedure was as follows: We folded a white towel, and along its upper edge poured on the chloroform. The lower edge was held under the patient's chin, our hands pressing firmly on the angles of lower jaws and well forward, watching carefully the patient's appearance and breathing, and admitting plenty of air.

Now I have come to modify my views. During the war I did the work of our senior medical officer in a large Midland town in order to release him for service in France. During the two years and a half I performed about 250 operations for tonsils, adenoids, and minor operations. My favourite anaesthetic was a mixture of three parts pure ether and one part chloroform, and only once had I to resort to artificial respiration and pituitrin. In that case the right tonsil when suddenly the patient stopped breathing; the pupils were widely dilated and the patient's appearance was like death. My assistant at once began artificial respiration and I injected pituitrin.

Allow me to say how much I enjoy reading my British Medical Journal. It seems to me to be much more interesting than it was twenty-five years ago. I only wish other general practitioners would give of their valuable experience.—I am, etc.,

Andover, Hants, July 8th.

Geo. A. WOLFENDALE.

Sir,—From the discussion on anaesthetics, lately taking place in your columns, it would appear that chloroform is the better anaesthetic; securing "quietness and relaxation," requiring but little sickness, and producing no bronchial irritation and little sickness. Either appears, statistically, the safer, and, in motoring terms, the more "fool proof."

The question now practically resolves itself into this: Is ether so much more satisfactory than chloroform that it should replace it?

On June 28th an inquest was held on the cause of death of two patients. They had died through the nurse having administered an overdose of atropine prior to the administration of ether. Chloroform requires no atropine. About the same period the patient was anaesthetized with ether in a leading London hospital by a skilled anaesthetist. Vomiting occurred, the anaesthetic was pushed, respiration was obstructed and stopped, tracheotomy and artificial respiration were performed, and the patient died of pneumonia complication two days after, consequent on the administration of the anaesthetic. Some years ago my wife was given ether in London prior to a mastoid operation. She vomited after a week after, admitted, admittedly on account of the anaesthetic.

and gave fears were entertained for her life, from that cause alone. I recall a series of letters by the late Mr. Clement Lucas, then surgeon at Guy's Hospital, on the danger of pneumonia after ether administration. In my letter of June 22nd I wrote: "Either lets off the anaesthetist, but is often inconsiderate to the patient, and I doubt, if after-effects could be taken into account and tabulated, whether ether would not present the darker picture." The illustrations I have given justify, I think, that statement. Why should our patients be made so sick, why injected with morphine and atropine, why handed over to unskilled persons to anaesthetize?

If chloroform be pure, administered on a Skinner's mask, held at first six inches from the face and only gradually approached, if occasionally a few drops of ether be sprinkled on; if morphine be never given, so that the pupil be free to react and be conscientiously watched, while the palpebral reflex is kept just absent, I doubt if misadventures with chloroform would occur more often than fatal complications with ether. If that be the case, why totally discard the better anaesthetic for the second best? We may have to do it because of the administrators of anaesthetics. The marvel is not that chloroform kills, but that it does not do it often. That is, I believe, why ether is popular abroad. I have seen a patient succumbed abroad, and held down while struggling for air till relaxation was produced, the mask being held tight down too.

Dr. Herbert Tilley says that the two misdeeds with his patients occurred when two well known experts administered the chloroform. Minor ones would have avoided, perhaps of surgeons, which blunt ones would have avoided. Why not use blunt ones? Because, though they escape the misdeeds they bruise the tissues, cause after-troubles not less tragic though less spectacular, and embarrass the surgeon.

Chloroform, too, is a sharp-edged knife, but, personally, I have found it in every way a more convenient and controllable anaesthetic than ether, requiring no adjuvant, inhalation by the patient in far smaller quantity and far less cold, and causing less irritation, sickness, and after-trouble. Why should I and others discard chloroform for ether, which has more drawbacks and possibly equal dangers? Let the specialist teach the student how to administer chloroform safely and properly, and ether reasonably.

—I am, etc.,

Knowle, Topham, Devon, July 7th.

D. W. SAKWAYS.

Sir,—The Research Defence Society has issued an essay on vaccination by Mrs. Schriebe, and a short leader for general distribution. The secretary will gladly send copies of the essay and of the leader to all applicants. Address, 11, Chandos Street, Cavendish Square, London, W.1.

The Society has already distributed a very large quantity of the leaders, and will gladly supply any amount of them. —I am, etc.,

London, W., July 2nd.

STEPHEN PAGEY, F.R.C.S.

## Obituary.

HARRY SHORE, M.D., D.P.H.,

Medical Officer of Health, Walsall.

We regret to record the death, in tragic circumstances, at the age of 52, of Dr. Harry Shore, medical officer of health for Walsall for the past fourteen years. Dr. Shore met by chance the superintendent health visitor in his department, who was riding a motor bicycle. Dr. Shore was much interested in motors, having been one of the first persons in the district to drive a motor car, and suggested trying the motor bicycle. Unfortunately, the end of his coat caught in the driving wheel and he fell to the ground, fracturing the base of his skull. Dr. Shore was educated at Queen's College, Birmingham, and Durham University, and at the latter he graduated M.B., B.S. in 1892, and M.D. in 1895, and took the D.P.H. in 1894. He was formerly in general practice in Walsall, and held the appointment of sanitary surgeon to the Walsall Hospital for some seven

from excision in aiming at a stable, strong, mobile, and painless joint. The new joint should be reasonably free from future complications. There were two indications for arthroplasty—to improve function and to diminish pain. Pioneer work carried out by surgical enthusiasts was often experimental and bore little relation to the problems arising in surgical practice. The fact that a stiff joint had been made to move might be more satisfactory to surgeon than to patient, whose interest was whether he could now do things and whether his limb was painless. In the lower limb he was strongly of the opinion that ankylosis of any individual hip, knee, or ankle in good position was preferable, both from the view of function and of pain, to the results obtained from any form of arthroplasty. After reviewing last year 2,000 children suffering from hip disease he knew that boys and girls with bony ankylosis of the joint could walk far better than those without. He would always prefer an arthrodesis as the operation of election in such a joint. Only in those cases in which there was double ankylosis of both hips, or of hip and knee, was arthroplasty desirable. Unfortunately, there were often especially difficult cases—those terrible instances, for example, of spondylosis rhizomyelia, when both hips and perhaps both knees were stiff and often painful. In these cases the inflammatory process went on in the new joint and produced persistent stiffness and pain. He was not sure that an ankylosis of both hips in abduction and 35 degrees flexion was not the most satisfactory end in these cases. The problem was very different in upper and lower limbs. In hip and knee, weight-bearing joints, it was very difficult to get satisfactory movement. In shoulder and elbow it was easy to get free movement, but difficult to provide good function. The shoulder was difficult; its mechanism was complicated. He noticed it had been much neglected by enthusiasts. The elbow was easiest and gave the best results. Indications were ankylosis in extension; painful movements not due to inflammation; exceptional cases where movement was required for occupational reasons. Mr. Elmslie then described his technique in operating on the elbow-joint. Active movements were permitted as soon as the wound was healed. A flexing sling was used.

Sir W. I. DE COURCY WHEELER (Dublin) said that arthroplasty of the shoulder was preferable to fixation if movements of the scapula were limited and the deltoid sound. In working men a fixation operation was best. In these operations a painless result was all-important.

Dr. JIASEK (Prague) indicated that in arthroplasties done in Professor Kukula's clinic in Prague the interposition method was used: omental fat was used in 9 cases, subcutaneous fat in 7 cases, free fascia in 9 cases. Results showed that in 13 knee operations there was a return of complete mobility in 77 per cent., in 9 elbow cases 88 per cent. were entirely satisfactory, in 2 finger arthroplasties and 1 hip there was a 50 per cent. and 0 per cent. recovery of complete mobility respectively. Re-ankylosis was due to a return of the purulent or specific inflammation and to insufficient will of the patient during post-operative treatment. In interposition methods hope of a good result must not be bought at the expense of such an extensive resection as to cause a flail joint. He preferred fat grafts, easily obtainable by doing a small laparotomy, if subcutaneous fat were insufficient.

Dr. STONEY of Dublin advocated excision of the elbow in certain cases.

Dr. TURRIER suggested the use of a small metal hinge, attached to adjacent bones, to keep the joint surfaces at a uniform distance apart.

Dr. A. JUNEZ (Poland) based his experience upon work done in Payr's clinic, where he had seen 150 cases of mobilized joints, and upon 24 operated cases of his own. There were patients who showed great pluck and energy before operation, and afterwards, owing to too early movements involving great pain, soon lost this early well-being. He considered a rational psychological treatment before and after operation of the first importance. In elbow cases he began movements not before a week after operation; in knee cases after two to three weeks; in hips after four weeks. In the meantime the limb was splinted or in plaster. The first movements merely consisted in changing the position of

the extremity in the operated joint once or twice a day. As to the time after an infection of the joint in which it was permissible to operate he used a simple test. Hyperaemia was administered to the joint, best by diathermy. Swelling and pain indicated an infective process. He removed the diseased synovia and all cicatricial tissue, but was very careful to spare as much as possible of the soft tissue—especially the lateral ligaments. It was important to remember the stabilizing effect of the ilio-tibial band in the knee-joint. For hip operations he used Ollier's incision and chiselled off the great trochanter; in knee mobilization the longitudinal S-shaped incision of Payr with separation of the vastus medialis from the quadriceps and fixation of the patella externally. He had learnt that day to use Putti's incision in rare cases where there was insufficient room. The elbow and hip gave the best results.

Drs. VILARDELL, CORACHAN, RIBAS y RYBAS, PINZI y SUREDA (Barcelona), and ZAMRADNICKY also spoke.

### INJURIES TO THE PERIPHERAL NERVES.

Dr. HENRIKSEN of Skien opened the third discussion. He said that much loose work had been done on nerve regeneration. Histological restitution was not proved to exist till nerves had been discovered of the same type as the nerve fibres, with axis cylinder, medullary sheath, and neurilemma nuclei. The process of regeneration must be followed up to the very formation of fully organized myelin fibres. Careful investigations of the conductive power of the nerve must be carried out. After a peripheral nerve had been cut with a sharp instrument it showed a pronounced disposition to heal spontaneously without leaving any permanent injury. Sensibility reappeared as soon as there was contact between the nerve ends, and motility in the course of two months. A similar return of function occurred as in spontaneous healing if the suture had been correctly performed with good adaptation and no tight knots.

Healing might be prevented as a consequence of the nerve ends being separated by displacement in other strata, by interposition of fat, or cicatricial tissue the result of infection. After a properly performed secondary suture return of sensibility set in at once. Motility and electrical reaction might appear in the course of two months and develop almost as after primary suture. If the nerve had been injured by blunt force, crushing, or tearing, the neurilemma nuclei were injured and part of them completely destroyed. Many of the newly formed nerve fibres were incapable of living and degenerated again. If the neurilemma nuclei were destroyed no new nerve fibres were formed and the nerve atrophied. The changes were most pronounced at the very spot of crushing where the nerve adhered to its surroundings. Improvement might be obtained in some cases by freeing the nerve and resecting the thickened fibrously infiltrated part. Then such degree of function was secured as the general condition of the nerve rendered possible.

Dr. GOSSET of Paris presented a table showing his war results in the various nerves operated upon. The percentages were of cures or of considerable amelioration of symptoms.

| Nerve.                  | Freeing of Nerve. | Suture.   |
|-------------------------|-------------------|-----------|
|                         | Per cent.         | Per cent. |
| Radial ...              | 95                | 45-55     |
| Median ...              | 47                | 44        |
| Ulnar ...               | 43                | 17        |
| Great sciatic (1917) .. | 55                | 35        |
| (1920) ..               | —                 | 40        |
| External popliteal ...  | 66                | 70        |
| Internal popliteal ...  | —                 | 40-50     |

The radial nerve was particularly favourable to regeneration. Even if the regenerated fibres had not passed down as far as the hand most of the muscles were reinnervated. Moreover, the nerve was so far from large vessels that a missile rarely wounded at the same time nerve and artery. Circulatory troubles and causalgia seldom developed in cases of radial paralyses. All other nerves could be said to give very variable results. Causes of failure were of three types. First, there was the defective operation.

## Medical News.

The University of St. Andrews will celebrate the installation of Mr. Ruyard Kipling as Rector by conferring the honorary degree of LL.D. upon a number of distinguished persons, including Sir John Bland-Sutton, President of the Royal College of Surgeons of England, the Prime Minister, and Mr. Kipling himself.

The Council on Medical Education and Hospitals of the American Medical Association reports that the number of medical schools in the United States is now 81, a decrease of two from last year due to the closing of two nonaccredited medical schools. The number of medical schools at the present time is exactly half the number that existed in 1906, when there were 162. The number of medical students during the present year is estimated to reach a total of 17,700, the largest number enrolled since 1912. In 1919 the total was 13,052, of which was the lowest number recorded since 1890, but of this number approximately 50 per cent. possessed higher educational qualifications as compared with only 6.2 per cent. in 1904. The average age of the medical students who graduated in 1922 was 26.8 years.

The trustees of the fellowships founded as a memorial to the late Sir William Ramsay, F.R.S., Professor of Chemistry at University College, have made their awards for 1922-23. Since the institution of the trust in 1919 twenty-one fellows have been appointed and nine others have so far been nominated this year. Among the appointments is that of a Norwegian fellow of £5,000 known to Mr. Gunnar Weidmann, to work at Cambridge under Professor Gowland Hopkins. Information received with regard to the present position of earlier fellows shows that most of them are now occupying important posts.

The Ministry of Health has drafted Regulations as to the labelling and composition of dried milk on the lines of the Regulations recently made with regard to condensed milk. Copies can be purchased under the description "Draft of the Public Health (Dried Milk) Regulations, 1923," from H.M. Stationery Office, or through any bookseller (price 2s.). Any representations on the subject should be addressed to the Secretary to the Ministry at an early date. The Regulations are intended to come into operation on January 1st, 1924, and will apply to all dried milk intended for sale for human consumption in England and Wales.

Professor Rogers has been re-elected Dean of the Faculty of Medicine. Professor Pierre Marie will resign his chair in the Faculty on August 1st.

A gift of 150,000 dollars by Mr. John D. Rockefeller, jun., is to be distributed among fifteen hospitals in the United States and Canada for the purpose of promoting the use of insulin in the treatment of diabetes. The hospitals will be selected from all parts of the country.

The second International Congress of Military Medicine and Pharmacy was recently held in Rome, when the following subjects were discussed: (1) carrying out of evacuations; (2) collaboration of civil and military authorities for the protection of public health; (3) methods of disinfection and distinction.

An All-Russian Congress for combating venereal diseases was held at Moscow from June 6th to 9th. The fourteenth Congress of Homeopaths was recently held at Moscow, under the presidency of Professor N. N. Zhelezniakov, Director of the State Institute of Homeopathy, and was attended by representatives from America, Bulgaria, China, Czechoslovakia, Holland, Hungary, Italy, Japan, Jugoslavina, Norway, Rumania, Spain, Switzerland, and Turkey.

Sir Huxley Rolleston, K.C.B., President of the Royal College of Physicians, has accepted an invitation to join the honorary medical board of Lord Mayor Trevellick Hospital, Glasgow, Scotland.

The William Gibson Research Scholarship of the Royal Society of Medicine has been awarded to Miss M. Forrester-Brown, M.D., of Dundee.

The seventeenth French Congress of Medicine will be held at Bordeaux from September 27th to 29th. The subjects for discussion include: (1) Remote sequelae of malaria, by Dr. Broderie, of Brussels; (2) relationship of the sympathetic system and the endocrine glands in pathology, by Professor Pachon and Dr. Ferrin; (3) treatment of meningococcal infections, by Professor Dopfer and Dr. Boudin.

Transplants, in spite of the brilliant results of the experimentalists, had been a failure. It was his opinion that after the lapse of five years the question of re-exploration should be considered in all cases of total failure.

Dr. CHIASSERINI (Rome) read Dr. Verga's paper. Perfect recovery after nerve injury was very rare. The percentage of improvement and of recoveries obtained by the writer in 82 cases observed for longer than one year after intervention were: 52.4 per cent. of recoveries, 37.8 per cent. of improvements, and 9.7 per cent. negative results. Out of 82 cases observed up to six and a half years after operation, only once a change for the worse had been observed, and only once restoration stopped. In all the cases improvement had been the rule, which showed that improvement was a question of time. The results obtained from suture and neurolysis were quite superior to those of all other operations.

Dr. LERICHE of Lyons expressed himself as being more and more convinced that causalgia was the consequence of a peripheral sympathetic lesion, or, if they preferred it, a vasomotor syndrome. In wounds involving arteries it was not the arterial lesion, but the periarterial sympathetic which mattered. Causalgia could be produced through the accidents and wounds of civil life. The malady, like any other of vasomotor origin, had two phases—a peripheral and a radico-medullary type. Operation could relieve the first phase. In the second radicotomy was not always sufficient and a chordotomy was sometimes necessary. Of peripheral operations he had had experience only of sympathetomy. Failures came through allowing the disease to enter on its later type and through operating in the wrong place. He had sometimes used heterografts of veins from calves or rabbits. An autoplasmic graft was much preferable to the dead heteroplastic graft of Nageotte. To cause trophic symptoms in limbs it was necessary to add trauma to an already existing nerve trouble. Resection of the neuroma and simple liberation was followed by temporary cure; resection followed by reconstruction had led to cure in favourable cases. For trophic limbs he recommended periarterial sympathetomy or the reconstruction of the nerve by graft, with or without sympathetomy.

Mr. PLATT of Manchester and Mr. BRISROW (London) presented the British report.

Mr. PLATT said that there was no doubt that results in general had fallen below their earlier expectations. He gave a list of true end-results in 157 suture operations collected by Professor J. S. B. Stopford of Manchester. (See table above.) Even in radio-spiral nerve recovery,

the best of any, normal synergic action of the extensors of the wrist was lacking. Neurolysis should be regarded as a necessary step in every efficiently conducted exploration and repair of an injured nerve. In cases of failure and partial failure after operations on the musculo-spiral nerve the results of tendon transplantation had been strikingly good. In this operation the pronator radii teres was transplanted into the extensor carpi radialis, longior and brevior; the flexor carpi ulnaris into the extensor communis digitorum and extensor longus pollicis and the flexor carpi radialis into the extensor ossis metacarpi pollicis and extensor brevis pollicis.

Mr. BRISROW quoted with approval the report published by the Medical Research Council in 1920: "Lateral implantations and flap operations are only mentioned here to be condemned." With regard to pathology an interstitial fibrosis and an ascending toxic neuritis occurred in the nerve proximal to the injury. Distal to suture occurred a tissue reaction due to the stitch itself and to sepsis, even when mild, fibrosis and shrinkage of the neuroma after its formation, and compression by fibrous tissue.

Mr. YOUNG of Glasgow presented reports of over 300 cases. He spoke of the technique of nerve operations. The parts should be disturbed as little as possible consistent with thorough liberation of the ends. Nerves should be dried in the air as little as possible. Thin catgut should be used. He regarded the use of a non-absorbable material such as silk unjustifiable in nerve suture. Sheathing of the reunited nerve might be accomplished with vein, fat, muscle, fascia, tendon sheath, or other material. He believed the best form of sheath was made from loose fatty tissue taken from the vicinity of the wound or the chest wall. He thought there was a fundamental error in thinking of the mechanism of nerve repair as different from that of other tissues. It was really the same. In it they must depend on the vitality of the essential cell of the tissue involved. Hence minimal operative trauma in order to avoid muscular interference and perfect asepsis must be the surgeon's aim.

Dr. CHIASSERINI of Rome discussed the question of grafting. He believed that many of the poor results observed in men after nerve grafts were due to faulty technique; the use of too thin grafts; primary tubulization of fresh grafts; suture not correct; adhesions preventing normal growth of fibres, and no after-treatment. He agreed with Elsberg in saying, "the era of peripheral nerve surgery is still to come."

EPITOME OF CURRENT MEDICAL LITERATURE.

**icing.**

Non-diabetic glycosuria.

**Non-diabetic glycosuria.** LABBE (Paris *med.*, May 5th, 1923, p. 411) remarks that in addition to diabetes mellitus various disturbances may occur due to changes in the function of sugar regulation glands, kidney, and especially liver, which are not far removed from diabetes as regards its evolution. In diabetes the disturbance in the regulatory apparatus is usually

67. Subcutaneous Fibroid Nodules in Rheumatism.

*M. D. Sc., June, 1923, p. 781) discusses cases more than the diagnostic value of subcutaneous fluid nodules in several of the more important infections. Varying in size from that of a pin point to a pea or even 1 or 2 centimeters in diameter, they occur most frequently in easily irritated sites—for example, the olecranon or occiput—and they appeared at the site of actual injury or contact with a foreign body. They are characterized by tenderness and the appearance of the surrounding subcutaneous tissues, commonly the thickening of the skin over the lesion. The appearance of the lesion may be described as resembling a pea or a marble. They are attached to the skin and are freely movable. They are not tender or red, and are usually freely movable. Composed of fibrin which can be detected early on moving the skin over the suspected area, and a clear, a small mobile feeling different from most skin nodules. They are usually isolated, but may be multiple. In the case of pyoderma, the characteristic thickening of the skin over the nodules, may not be so great as in the case of pyoderma. They occur generally in those subjects in whom the infection is only but occasionally developing, a crippling stenosis, damage to the general circulation and a systemic, but occasionally developing, little or no fever or other joint symptoms. They occur rarely. Such recurring nodules are of a great variety of origin, but are of value in the diagnosis of a few of the more important infections. A significant result in great percentage of cases; of the 59.5 per cent. were fatal, and of 44.7 per cent. of the 59.5 per cent. were fatal, and of 44.7 per cent. of the 59.5 per cent. were fatal. Such occurred in only one instance in which nodules were not present.*

## The Heart in Diphtheria.

Dr. Lott (*Arch. Int. Med.*, May 15th, 1921, p. 657) reports a study of the heart in 117 children, 100 of whom had pathological changes, although only 58 were relatively free from serious heart symptoms. He observed with interest that the pathological changes were observed with the same frequency in the coronary arteries as in the aorta, and that the changes in the coronary arteries were more extensive than those in the aorta. He also found that the changes in the coronary arteries were more extensive than those in the aorta. He also found that the changes in the coronary arteries were more extensive than those in the aorta.

71. Thoracoplastic Lung Compression in Pulmonary Tuberculosis.

P. K. Brown and L. Bloesser (*Arch. Int. Med.*, May 1933, p. 70) emphasize the primary value of rest in treating tuberculosis, the five methods producing relative immobilization of the lung being: (1) lying for 23 hours a day on the affected side or with sandbags thereon; (2) section of the phrenic nerve to paralyze one-half of the diaphragm, to allow partial collapse of the lower lobe; (3) local replacement of the area affected after external drainage of the abscess; (4) collapse of the lung by gas, or air, introduced upon readmission of the patient to the hospital; (5) resection of all parts on one side to cause narrowing of the chest commensurate with the equivalent collapse. Notes of the cases are given in which the thoracoplastic compression was performed, with improvement in all, and different contraindications in which it cannot be carried out effectively.

The case is of interest in the study of disturbances and their possible effects on the skin.

Plastic 70.

author considers Still's disease to be probably the result of polyarthritic affections, do not occur in skin diseases.

Still a Disease.

though fat accumulation and cloudy swelling are fairly regularly observed, these appearances are not more pronounced than in other acute affections, such as scarlet fever, measles, or pneumonia. Degenerative changes in the cardiac muscle by pronounced fat accumulation in the fibres, similar to those seen in the human heart in fatal cases, follow the injection of diphtheria toxin in guinea-pigs. Of 45 cases of diphtheria (5 per cent.) were fatal, and the above findings are based upon data furnished by 19 which came to necropsy.

Parliament, under vote-catching influences, can ever again be relied on to give reasonable protection to the house owner, or by these causes in combination and other causes besides? If so, if things have come to such a pass that houses for the industrial classes will no longer be built privately, then, indeed, provision for wage earners becomes a definite and permanent public responsibility, central, local, or both. It is a stupendous task, which it might never have been necessary to face but for foolish legislation. At the Annual Meeting in Glasgow last year Dr. F. E. Fremantle, M.P., discussed the economics of public health,<sup>1</sup> and urged that even financially its further advancement would be a profitable investment. He was fundamentally right, but in providing houses the State will have enormous difficulty in preventing the taxpayer and ratepayer from being fleeced as they were when Government took up the matter before. In our issue of August 26th last we wrote: "When, two or three years ago, the politicians and the press and the public outvied each other in their shoutings for houses, what was the result? The Government took up the matter, and with the enthusiastic support of builders and brickmakers and bricklayers entered on a course of reckless extravagance, which was brought to a stop when the nation came to realize that this was a post-war method of fleecing it, such as had hardly been surpassed by the great army of profiteers during the war itself. Straightway prices began to fall, and now houses can be built for a half, a third, or even a fourth of what the country had to pay for grandiose schemes which played into the hands of extortionists." A similar difficulty will certainly emerge in similar circumstances, and Government must be fully prepared to deal with it if, as it ought, it tackles the whole subject of housing on the lines suggested in the President's address. No more impressive argument for facing the situation boldly and speedily has been advanced than that which he brought before his medical audience, and through it, before the public.

### THE GRADUATE'S DEBT.

SIR SAMUEL WILKS was fond of quoting Bacon's saying, "I hold every man a debtor to his profession; from the which as men of course do seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto." Sir Harold Stiles, had he remembered it, or perhaps had he not had other quotations less hackneyed, might with a slight restriction have taken it for the text of his address as promotor of the new graduates at the summer graduation ceremony of the University of Edinburgh last week. The old custom in Edinburgh was that the graduate being capped—with a cap made, by a lively combination of sentiment and economy characteristic of the country, from the velvet breeches of George Buchanan, historian and poet—was promoted to the platform. Nowadays there are too many for this physical promotion; there were over 200 last week in medicine alone, and the promotor was content to impress on his audience in the body of the M'Ewan Hall the spiritual meaning of the promotion they had metaphorically enjoyed.

It was perhaps temerarious of the promotor in addressing newly capped graduates, whose brains

would be fuller than their pockets, to make an appeal for money, but there is a sort of man who may steal a sheep and another sort who may not look over a gate. Doubtless Sir Harold Stiles belongs to the former sort, and doubtless, too, he had in his mind's eye a larger audience of Edinburgh medical graduates who have crossed the Tweed and sailed the seven seas to seek and find fortune. We have done our best to second his appeal by giving at page 159 a full account of what he had to say about the Alumni Associations of American universities. Barring the name, which is alliterative but not euphonious, they are organizations which deserve the compliment of imitation. American universities have been happy during the last two or three generations in winning the sympathy of rich men whose ambition it has been to found, not a family, but a place of study, a *studium generale*. But the notoriety of these immense benefactions has perhaps obscured what the graduates themselves do to strengthen the interest in learning and the strong sense of fellowship the universities foster.

The organization of graduates in America is twofold, and the one cuts across and supplies the deficiency of the other. There are the fraternities known usually, we believe always, by three letters of the Greek alphabet chosen apparently at random. Membership is not confined to any one university, but their portals are jealously guarded, and eligibility for admission would seem to depend primarily on the candidate's academic distinction. Their aim is mainly to promote good comradeship, and, as far as possible, to ensure to a travelling member in all the chief cities a sort of club where he may expect to meet men of his own kidney. They recall one side of the work of the mediaeval guilds, which made it possible for a wandering craftsman in a strange town to fall in with his fellows, to be comforted by them, and to learn from them. The other kind of organization, one more adapted to conditions in this country, is the Alumni Association. Of what such a body can do Sir Harold Stiles gave several examples. In an American university a great deal is made of graduation, or, as they perversely call it, commencement day. On that day all graduates of the university are welcomed by the officials of the university; here, except at Oxford and Cambridge, where collegiate life is strong and where a man can keep his name on the books of his college until the end of his days, the old graduate is like a fish out of water; the authorities know him not, neither do they care a pin about him, and it will be a pure chance if he runs across any man of his year. There are annual dinners of universities or medical schools, and the Scottish university graduates have dining clubs in several English centres, but they are unsatisfactory and ineffective substitutes for the American Alumni Associations, which have found many ways of preserving and stimulating the sense of corporate unity. The promotor suggested that a beginning might be made in Edinburgh with the medical alumni, and invited the General Council of the University to consider how the matter might be brought within the sphere of its activities.

Sir Harold Stiles had his sheep to steal, and we hope he may get clear away with it. The Simpson Memorial Hospital is a good intention ill fulfilled. That Edinburgh has no adequate maternity hospital in which its students can be taught preventive and operative midwifery is a reproach to the city, to the university, and, if we accept the doctrine of the Professor of Clinical Surgery, to its alumni also.

D'Ewart remarked that the weakness of criticism so emphatically offered might be taken as a very fair index of the strength of the position attacked. In any case, an attack founded in part on an alleged omission from the report of any estimate for the current financial year could hardly be effective. The criticism offered by Hastings, based only upon the increase in the volume of expenditure since 1920, lost its force in the atmosphere created by the earlier discussion, quite apart from the fact that, in avoiding the risks of concrete criticism, it suggested no practicable methods of effecting the desired economy. Dr. Rose's far stronger appeal for economy, based upon the burden of expense to the individual member, would have failed for the same reason, but the real reply to his contention was voiced by Dr. Peter Macdonald when he pointed out that to cut down expenditure as long as each additional outlay is producing an increasing return is economically unsound. The discussion on the relations between the Association and medical charities, introduced by Dr. Dearden, struck an unexpected note in criticism. The present position, as indicated by the Treasurer, is obviously unsatisfactory, and since it can only be remedied by action on the part of the governing bodies of the charities—that is, ultimately by pressure from subscribers—ventilation of the subject amongst these should prove of value. As regards the new building for the Association headquarters, the Chairman of Council and the Treasurer, reinforced by Dr. J. A. Macdonald and Mr. Bishop Harman, had a light task. If the representatives did not meet in a state of enthusiasm they came fully prepared to take fire, and the final vote of approval was given unanimously and with acclamation. The report of Dr. Bolam's lucid and persuasive speech should be read by every member. The medico-political report raised relatively little discussion; what debate there was arose on points of substance, and served a useful purpose, if only as indicating the thorough way in which the Committee had worked over the field covered by its report. The criticisms and inquiries offered were based on real difficulties. There was substantial agreement in regard to several amendments covering procedure in connexion with the report of offences to the General Medical Council by the Home Office. Many representatives clearly found the existing conditions objectionable in theory, but, as pointed out by Sir Jenner Verrall, the difficulty was to discriminate between cases to be reported and cases not to be reported, and consequently the meeting had no alternative but to leave things as they are. Even in the matter of midwives and the use of drugs, on which warm feeling was displayed, the ultimate decision left the Association's position unaltered. So, again, with the obligation of notification of births without remuneration. It was unfortunate that one motion of considerable interest, put forward by Dr. Noy Scott and Mr. Russell Coombe, was not on the agenda paper, and was adopted without attracting much attention. This was the resolution in favour of consultation between medical witnesses in the

courts, especially in compensation cases, with a view to agreement on questions of fact prior to giving evidence for either party. The only point at which any acrimony was displayed was in connexion with the paragraphs of the Council's report dealing with the affairs of nurses. However, the meeting, directed to the real issue by Sir Jenner Verrall, refused to question the Committee's action.

#### GIFT TO NAVAL OFFICERS' MESS.

The Exhibition at the Annual Meeting is being held this week in the Gymnasium of the Royal Naval Barracks, Portsmouth, which has never previously been open to any association or body other than the Royal Navy. To mark this unique occasion, and to show the appreciation of the assistance rendered to the Exhibition by the authorities at the Naval Barracks, it was decided to offer for the acceptance of the President of the Naval Officers' Mess at the Portsmouth Barracks a trophy which it is hoped will take its place amongst the beautiful collection of silver possessed by that Mess.

The piece selected is an ewer, a reproduction of one of a very fine pair of ewers (wine and water) designed by John Flaxman, R.A., working under the inspiration of an ewer now preserved in the museum at Naples. Flaxman was born at York in the year 1755 and died in 1826, and from an invoice still in existence from Flaxman to Wedgwood and Bentley, these ewers appear to have been designed and modelled in March, 1775, and are among the first articles produced by the artist for Josiah Wedgwood. The wine ewer is of classic design and feeling, as may be judged from the photograph here reproduced. A bold goat's head is mounted on the front of the body under the lip, with festoons of leaves and grapes on either side. The neck is ornamented with ripples of water; seated on it and forming the handle of the ewer is the figure of a satyr with his arms round the neck clasping the horns of the goat. The lower part of the body is ornamented with a mounted laurel band and leaves, and rests on a hollow-fluted and

Silver Ewer presented to Royal Naval Officers' Mess, Portsmouth.

beaded foot, terminating in a low square plinth, decorated in panels with a form of key ornament.

The ewer, which is 16½ inches in height and weighs 126 troy oz., was reproduced and manufactured by Mappin and Webb, Ltd. The ewer was presented to the President of the Naval Officers' Mess by Mr. Charles P. Childe when, as President-elect, he formally opened the Exhibition on Tuesday morning, July 24th (see SUPPLEMENT, p. 76).

#### THE BOOK OF PORTSMOUTH.

EVERY member of the Association, on registering his or her name this week at the reception room at the Municipal College at Portsmouth, has received a delightful little volume issued as a souvenir of the Annual Meeting by the Printing and Publishing Committee.<sup>1</sup> The *Book of Portsmouth* is not in any sense a guide-book to the town and

<sup>1</sup> The *Book of Portsmouth*. Portsmouth: Charpentier, Limited. 1923. (Cr. 8vo, pp. 191, illustrated.)

INSULIN

DELIVERED TO  
A GENERAL SESSION OF THE FIFTEENTH INTERNATIONAL  
PHYSIOLOGICAL CONGRESS, EDINBURGH,  
J. J. R. MACLEOD, M.B., CH.B., F.R.S.,  
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF TORONTO.

requesting for my collaborators, as well as myself, I wish to state you that we consider it a very great honour that an account of our researches on insulin should be given so prominent a place on the programme of the XIIth International Congress of Physiologists. In accepting the invitation to address you on this work, I fully realize the great responsibility that I have assumed, the more so since at present time there yet remains so much that is obscure and unexplained, particularly with regard to the physiological aspects of the subject.

There is no other problem in the whole vast field of medical sciences that has attracted such diverse groups of workers, as that of the relationship between the pancreas and disturbances in carbohydrate metabolism. Anatomists, physiologists, biochemists, and physicians have contributed much to it, each adding some new and fundamental fact, and the knowledge thus acquired has formed a foundation upon which the present investigations depend. I shall not occupy your time here with a review of this earlier work except in so far as it is essential to an understanding of its relationship to these investigations.

HISTORICAL

Towards the end of the seventeenth century Brunner, in his celebrated researches on the digestive functions of the pancreas, had occasion to remove the gland, and he described symptoms in the operated animals which were without doubt those of diabetes. This was, however, some time before the case had come to be recognized as a clinical entity, and was not until considerably later that physicians began to point out the frequent occurrence of morbid changes in the pancreas of patients who had died of it. The clue which is observation offered, suggested to experimenters, among them Claude Bernard, the advisability of seeing whether removal or destruction of the pancreas might cause diabetes. The experiments were without success until 1885, when von Mering and Minkowski announced their well known discovery, as a result of which Minkowski subsequently published a complete account of the pathological anatomy of the diabetic condition as observed in depancreatized animals. As the cause of the diabetes Minkowski suggested the removal from the organism of "a something" at its essential for the metabolism of carbohydrates. He early meant an internal secretion, although it is in the writings of Leding that for the first time we find this term actually used in connection with the pancreas. But the existence of an internal pancreatic secretion could not be considered as an established fact until it could be shown that the administration of an extract of the gland to depancreatized animals is capable of removing the diabetic symptoms, and this some of the investigators of this period would succeed in doing. These failures led some to suppose that the pancreas must control the metabolism of carbohydrate otherwise than by an internal secretion, although a majority considered that it was merely owing to destruction of the active principle during the preparation of the extracts that the failure to obtain it in extracts as due. At the same time as these experimental investigations were in progress most valuable work was being done on the minute anatomy of the pancreas, particularly with regard to the islets of Langerhans as distinct and separate from the secreting acini. Among these workers I cannot refrain from paying tribute to Laguesse and Diamant, among

RECENT RESEARCHES.

We may take up the recent researches on insulin at this point; they had their origin in a suggestion, made by R. G. Banting, that since it was probable that the failure due to the presence in them of proteolytic enzymes which would destroy it, the action of these might be circumvented by extracting glands that had been caused to undergo degeneration by previous ligation of the ducts. With the collaboration of C. H. Best, Banting ligated the ducts of the pancreas in several dogs, and a few weeks afterwards killed the animals by chloroform, quickly excised the partially degenerated residue of the gland, and extracted it with ice-cold Ringer's solution by grinding in a mortar with sand. Intravenous injection of the extract into depancreatized animals was found to cause prompt and decided lowering of blood sugar, accompanied by a fall in the sugar excreted in the urine without any change in the percentage of haemoglobin in the blood. That the treated animal had registered some of its lost power to utilize carbohydrates was demonstrated by comparing the sugar balance, following administration of a measured amount of sugar, with and without the extract. Incubation of active extract and administration of a measured amount of sugar, with

occasional success. The most successful attempts to prepare pancreatic extracts containing insulin were made by Zuelzer, who, in 1908, showed that alcohol extracted from pancreas which had previously been subjected to a certain degree of change by ligation of its veins, a substance which was capable, when injected subcutaneously, of preventing the rise in blood sugar and the glycosuria which ordinarily follows injection of epinephrin. Zuelzer carried his investigations far enough to show that alcoholic extracts of beef pancreas could also remove many of the symptoms of diabetes in man, but, unfortunately, he failed to establish the therapeutic value of his product because of certain toxic symptoms which followed its administration. It is possible that these may have been due, in part at least, to an excessive lowering of the blood sugar which we now know to be associated with peculiar symptoms. From this time on the problem of attempting to produce extracts of the pancreas containing insulin fell to the lot of experimenters, among whom may be mentioned Knowlton and Stalling in this country, and E. L. Scott, J. R. Martin, Cramer and I. Kleiner in America, but with only occasional success.

But all this evidence, strong though it might be, could not be considered as affording positive proof that the pancreas produces an internal secretion necessary for the control of the metabolism of sugar, and renewed attempts to demonstrate its presence in pancreatic extracts did not meet with sufficient success to prove convincing. That this would ultimately be achieved, however, was apparent to many, and to none more so than to the President of this Congress, Sir E. Sharpey Schaffer, who, by suggesting the name Insulin for the hormone, indicated his belief that its source is the islets of Langerhans. The most successful attempts to prepare pancreatic extracts containing insulin were made by Zuelzer, who, in 1908, showed that alcohol extracted from pancreas which had previously been subjected to a certain degree of change by ligation of its veins, a substance which was capable, when injected subcutaneously, of preventing the rise in blood sugar and the glycosuria which ordinarily follows injection of epinephrin. Zuelzer carried his investigations far enough to show that alcoholic extracts of beef pancreas could also remove many of the symptoms of diabetes in man, but, unfortunately, he failed to establish the therapeutic value of his product because of certain toxic symptoms which followed its administration. It is possible that these may have been due, in part at least, to an excessive lowering of the blood sugar which we now know to be associated with peculiar symptoms. From this time on the problem of attempting to produce extracts of the pancreas containing insulin fell to the lot of experimenters, among whom may be mentioned Knowlton and Stalling in this country, and E. L. Scott, J. R. Martin, Cramer and I. Kleiner in America, but with only occasional success.

arrangements for the comfort and safety of passengers and crew were much admired; special interest was shown in the medical equipment, the swimming bath, and the apparatus for enabling passengers to take active exercise during an ocean voyage. After this tour of one of the largest liners afloat, the party made their way back to the little *Duchess of Fife*, and found tea ready to be served on board during the return journey. Southsea was reached in time for dinner, and it was generally agreed that a delightful day had been spent.

### THE INTERNATIONAL SURGICAL CONGRESS.

The meeting of the International Surgical Congress in London, the early proceedings of which were reported last week (p. 121) came to an end on Friday, July 20th. We publish this week reports of two more of the discussions—one on arthroplasty, which was well sustained and excited a great deal of interest, and the other on injuries to the peripheral nerves. The meeting, under the presidency of Sir William Macewen, was in every way a great success. A general meeting of the Society, very largely attended, was held, with the President in the chair, on July 19th, when it was decided that the next congress should be held in Rome, and not in Warsaw as had been proposed. Dr. Davide Giordano of Venice, was elected president. Votes of thanks to Sir William Macewen for his services as president, to Dr. Leopold Mayer of Brussels, general secretary of the Society, and to Sir D'Arcy Power and Mr. J. E. H. Roberts, the two British secretaries of the meeting, were proposed by Dr. W. W. Keen of Philadelphia, who expressed the feeling, shared by the whole Congress, of deep indebtedness to the secretaries for the able and particularly thorough way in which all arrangements for the convenience and comfort of the delegates and members had been made. A banquet was held on Friday evening, July 20th. Sir William Macewen, who was in the chair, proposed the health of the delegates, and expressed the pleasure he and his British colleagues felt in meeting so many representatives from different countries. The Society had received two invitations for the next Congress—one was from Poland. It was, Sir William Macewen said, a plucky thing for our Polish friends to do, and it showed that they had great faith in themselves; he hoped that if the invitation were repeated at some future date the Society might be able to meet in Warsaw. The next Congress, it was arranged, should be held in Rome, the capital of a country vibrant with scientific life. The toast was acknowledged by the spokesmen of several countries. Dr. R. A. Alessandri, Professor of Clinical Surgery in Rome, said that medicine was the only world-wide art, and that its universality was its most important attribute. In the modern Greece, as Osler had called England, the foreign members had received, and were most grateful for, abundant hospitality. Dr. Mayer, responding for France and Belgium, also expressed the gratitude of the foreign members and the hope that the *entente cordiale* of medicine might continue. Dr. Koch, who spoke for Holland, recalled the time when an English king was Stadtholder of Holland, and said that the Dutch would never forget the help given them by England in the time of Elizabeth, when their country was oppressed by Spain. Dr. Crile returned thanks for the United States of America, Dr. Hansen for Denmark, Dr. Petridis for Egypt, Dr. de Zawadzki for Poland, Dr. Kayser for Sweden, and Dr. de Quervain for Switzerland. In response to loud calls Sir D'Arcy Power and Mr. J. E. H. Roberts, the British secretaries, briefly and very modestly returned thanks. Mr. Roberts observed that Sir D'Arcy Power had been for twenty-two years and until last year British representative. A number of receptions, besides those mentioned elsewhere, were given during

the meeting of the Congress; on July 17th the men were received by Sir Charles and Lady Ballance, and the following evening by the Lord Mayor and I Mayoress at the Mansion House.

### MEDICAL RESEARCH IN INDIA.

The committee on retrenchment in India, over which Lord Inchcape presided, recommended, among other things, the payment of research officers from central revenue should cease, and that the grant-in-aid to the Research Fund Association should be discontinued. The association has accumulated 33 lakhs, derived from the Government contribution and earmarked for a new central institute at Delhi; the committee advised that the interest on this sum should be used for the maintenance of medical research. The *Pioneer*, which is commonly credited with being well informed as to the intentions of the Government of India, stated in its issue of June 7th that it was understood that the Inchcape Committee's recommendations regarding the continuance of expenditure on medical research will not be accepted in their entirety. The adoption of the drastic proposals put forward by Lord Inchcape and his colleagues would, our contemporary continues, have involved "the virtual closing down of all research work in India, for, in the face of such a curtailment of activity, the chances of obtaining research workers in the future would have been small indeed. As it is, there is ground for the belief that the policy to be adopted will be that of securing a state of suspended animation. Thus instead of abolishing the appointments of twelve bacteriological officers, as recommended by the Retrenchment Committee, it is proposed to leave six of these appointments unfilled until financial conditions are more favourable. The establishment of a central research institute at Delhi and the grant of five lakhs a year to the Indian Research Fund Association are similarly suspended. This measure of retrenchment will be regretted, but it, at least, will not render the position hopeless, and it provides the retention of a nucleus for expansion when the occasion is suitable. The Directorship of Medical Research has been abolished for the time being, but arrangements are being made for that officer's duties to be carried on departmentally." The *Pioneer* goes on to express the opinion that if its prognostications prove to be correct, the Government of India has been able "successfully to temper its obsession on the subject of retrenchment with a due appreciation of the vital importance of medical research in a country like India." We can only express a fervent hope that this interpretation of the situation may prove to be correct; it does not seem to be a particularly courageous manner of dealing with a matter of so much importance. As we observed when the Inchcape report was first published, it is a paltry piece of economy to cut down the relatively small sum provided for the scientific study of the causes which lead to the high mortality among the 350 millions of the population of India. The amount represents an expenditure of about one-twelfth of a farthing a head a year. The wisdom and policy of establishing a central medical research institute at Delhi is, we admit, open to doubt; it may be very much wiser to subsidize provincial institutes and special inquiries. It is easier to destroy than to build up, and even if a nucleus be retained the loss of experienced workers can hardly fail to make the eventual expansion more difficult.

### THE BRITISH ASSOCIATION.

The arrangements for the meeting in Liverpool of the British Association for the Advancement of Science are now far advanced. This will be its fifth meeting in Liverpool; the last occasion was in 1896, when Lord Lister was president.

given along with carbohydrate to depancreated dogs, very large quantities of glycogen become deposited in the liver and that the respiratory quotient becomes raised in the same manner as it does in normal animals with carbohydrate alone. We know also from the work of Banting and Best on depancreated dogs that it reduces the blood sugar to the physiological level, that the glycosuria disappears, and that the well-being of the animal becomes normal in every regard.

We must conclude, therefore, that insulin is necessary for the metabolism of carbohydrate, and we may suppose that its function is in some way related to the preparation of the glucose molecule for combustion and condensation. But as to whether this preparation consists in a change of  $\alpha$ ,  $\beta$  glucose into the  $\gamma$  variety cannot as yet be considered. Smith's observations, and by strictly following their instructions has obtained similar results. Briefly stated, these results are that after removal of the proteins by phosphotungstic acid and alcohol from normal blood, the dextro-rotatory power of the filtrate is lower than it should be as calculated from the reducing power, and on standing twenty-four hours the difference becomes less, and later they practically disappear. On the other hand, when blood from diabetic patients or hyperglycemic animals is used, the dextro-rotatory and reducing values correspond from the start, or the former may exceed the latter. Administration of insulin causes the diabetic blood to behave in these regards like normal.

The question is with regard to the interpretation of the results; as Hewitt has pointed out, this need not necessarily be that  $\gamma$  glucose is present, but rather that chemical changes have occurred in the very complicated procedure which is involved in the preparation of the solutions for the polariscope. Others have believed that the blood may contain, besides glucose, other carbohydrates or related substances having a relatively low dextro-rotatory power. Since this question is not yet settled I need not dwell on the further claim of Winter and Smith that insulin is capable of causing  $\gamma$  glucose to be formed when added to a solution of ordinary glucose along with an extract of liver. I may say, however, that we have so far been unable to confirm this result. The action of insulin on the metabolism of fat in diabetic animals is as striking as on carbohydrate, and here again its effects are revealed by chemical changes occurring at both ends, as it were, of the metabolic chain. In a few days after pancreatectomy in the dog, the blood and the liver contain excessive quantities of fat, although the extreme degrees of lipemia sometimes encountered in diabetic patients have not been observed. There is also a less pronounced than it is in diabetes in man. Evidently the migration of fat in the body is abnormal, and its final oxidation seriously interfered with. When insulin is given along with carbohydrate to these animals, the acetonuria very promptly disappears, the blood fat, apparently more slowly, returns to normal, and the liver in a few days contains no more fat than that of a normal, similarly fed animal. As the glycogen increases in this vicious fat correspondingly declines. We cannot state at which stage in the metabolism of fats insulin exercises its corrective influence, but wherever this may be there can be little doubt that it acts indirectly because of its effect on carbohydrate. It has been said that fat burns in the fire of carbohydrates, and although this generalization may, in some respects, be misleading, it is, nevertheless, a useful guide in interpreting the results with insulin.

# THE THERAPEUTIC EFFECTS OF INSULIN IN DIABETES MELLITUS.

As would be expected, the effects of insulin on patients suffering from diabetic mellitus, in so far as these have been studied, are of the same general nature as those observed on diabetic (depancreated) dogs. Until the laboratory investigations had furnished perfectly definite results no serious attempts were made to carry the investigations into the clinic, nor would it have been permissible to do so in view of the failures of previous workers to provide an extract that did not cause toxic symptoms.

Without animal experimentation we would be no further to-day in the treatment of diabetes, and in the undoubted saving of human life which has been the result, than we were a little over a year ago when the treatment was first applied on any considerable scale. In studying the results obtained by administration of insulin to patients, we must bear in mind that two factors may come into play that are not involved in the experiments on completely depancreated animals. One of these is dependent on the fact that there probably still remains in the majority of diabetic patients a certain remnant of pancreatic tissue capable of secreting insulin. The other is dependent on certain differences between laboratory animals and man, related in part to peculiarities in the type of metabolism and in part to the greater development of the nervous system, to which the frequent occurrence of coma as a serious symptom of the clinical form of the disease is due. Moreover, we must remember that subjective phenomena can be studied only in man.

The first case in which a complete study of the therapeutic value of insulin was made was that of a boy fourteen years of age, exhibiting all the classical symptoms of the disease; treatment by diabetic control had resulted in no improvement. Daily injections of insulin between January 23rd and February 4th, 1922, reduced the blood sugar, even to the normal level, greatly diminished the glycosuria, and often caused it to disappear, removed entirely the ketonuria for a period of some days, and, perhaps more striking of all, "the boy became brighter, more active, looked better, and said he felt stronger." There could be no doubt as to the great therapeutic value of the treatment when judged both by the improvement in the objective and subjective symptoms of the disease. This, along with other cases treated by insulin, and reported by Banting, Best, Collip, Campbell, and Fletcher, is only the first of a large number, exhibiting the disease in all its forms, that have been most carefully studied in numerous clinics both in Canada and the United States and in Great Britain, and I cannot refrain from expressing my admiration for the excellent spirit of collaboration which has made this possible. I may say that there can be no doubt that insulin is capable, when wisely used under controlled conditions, of saving many cases of diabetes which would otherwise inevitably succumb to coma, or to one of the many other complications of the disease. It is also certain that as an adjunct to diabetic control, treatment with insulin greatly improves the nutritive condition and increases the resistance towards infections, thereby prolonging the expectancy of life. The subjective condition and the sense of well-being of the patients are also vastly improved. As to whether continued treatment with insulin will enable the diabetic patient to recover any of his lost power of producing this internal secretion in his own pancreas, nothing definite can be said at present. It is at least significant in this connection that the islet tissue develops considerable powers of regeneration after much of it has been destroyed as a result of ligation of the secreting ducts of the pancreas, as has been shown by R. R. Beasley to happen, at least in the rabbit and guinea-pig. Acting as it does in these cases from outgrowths of the duct epithelium, may it not be possible in man, in whom the pancreas has not been completely destroyed by disease, that new islet tissue will become regenerated when, by administration of insulin, the strain to produce this hormone endogenously is removed?

## THE EFFECT OF INSULIN ON THE BLOOD SUGAR OF NORMAL ANIMALS.

Returning now to the more purely physiological aspects of the subject, let me briefly lay before you what is known regarding the effects of insulin on normal animals. In the consideration of these results we must bear in mind that the conditions in the normal animal are fundamentally different from those obtaining in the diabetic. In the normal animal there is probably available at all times a sufficient amount of insulin for every purpose for which it is required, so that the addition of more from without

## IMPERIAL CANCER RESEARCH FUND.

As mentioned briefly last week, the annual meeting of the Imperial Cancer Research Fund was held on July 17th, when the usual business was transacted. We have already quoted the observations of the President, the Duke of Bedford, with regard to the relation of the Fund to the British Empire Cancer Campaign.

Lord Atholstan's grant to the Fund for research has been utilized by the appointment of Dr. A. M. Begg to carry out an investigation on the subject of the infective sarcomata (dogs and fowls) with a view to defining the difference, if any, between them and true neoplasms. Last March an anonymous donor founded an "Alice Memorial Fellowship" for cancer research under the auspices of the Fund, and recently Dr. Marshall Findlay has been appointed to be the first Fellow. The question of clinical research in cancer has been under consideration, and last December the directors of the surgical units in London were asked to discuss with a subcommittee the possible lines of such an investigation. Various proposals were considered, including an investigation into deep x-ray radiation, but further proceedings were postponed on account of the proposal to institute the Cancer Campaign. The director, Dr. J. A. Murray, presented his annual report:

REPORT OF DIRECTOR.  
Vitamins.

The investigations mentioned in the preceding Annual Report have been continued. Dr. Cramer's work on vitamin deficiency has been brought to a conclusion, so far as regards cancer, and will be treated as a whole in a paper in the forthcoming eighth Scientific Report, which it is hoped to issue in the autumn. Briefly, it can be said that repeated experiments, under the most stringent conditions, have failed to give any evidence of an inhibitory effect on the growth of cancer, even when the deficiency is so severe as to be incompatible with life. This apparently paradoxical result has been obtained with deficiency of both the water-soluble and fat-soluble vitamins separately and in combination. No experiments have been performed to test the effects of deficiency of the antiscorbutic vitamin C, as it was felt that this deficiency is too dangerous to life in man to permit of even a tentative application to the treatment of cancer in human beings. While a practical value in treatment is not to be expected in this direction, the results of these experiments cannot fail to have a considerable influence on our conceptions of the way in which vitamins act.

## Effect of Radiation.

The curious fact that the absence of vitamins from the diet produces atrophic lesions very similar to those produced by exposure to radiations from x rays and radium led to an investigation into the biological effect of radiations on the normal organism. In this investigation Dr. Moltram, of the Radium Institute, has collaborated with the workers of this Fund. It was found that exposure to radium has a profound effect on intestinal activities and that large doses may lead to severe lesions in the intestine. There is also an effect on the blood platelets which, if it is allowed to continue unchecked, is constantly associated with an incurable anaemia of the pernicious type. These observations on the effects of large doses of radiation are of importance in connexion with the therapeutic applications of radium and x rays. Small doses of radiation often lead to obesity. The manner in which this condition is produced has also been studied, and shown to be related to the testicular atrophy and hypertrophy of the interstitial cells.

## Tissue Culture.

Dr. Drew's tissue-culture work has been carried on energetically, and has added considerably to our knowledge both of normal and cancerous cell life. The phenomena of differentiation and loss of differentiation, as they appear in tissue cultures, have been reduced to an orderly sequence, and can now be reproduced at will. He has shown that differentiation is absent in cultures of normal tissues (kidney, skin) when the essential parenchyma cells are grown in pure culture without admixture of connective tissue. The addition of a pure culture of connective tissue to such a pure culture of kidney epithelium or squamous epithelium is quickly followed by typical histological differentiation—the kidney producing convoluted tubules with swollen bulb-like extremities, and the squamous epithelium keratinizing out in cell nests. It is practically impossible to maintain the exact balance between the two factors under the experimental conditions, as usually the connective tissue overgrows and suppresses the epithelial elements. Occasionally the epithelium obtains the upper hand, and it then grows as

before, as an undifferentiated sheet of cells. The sequence of forms presented by squamous metaplasia corresponds with the sequence of experimental results met with in squamous-cell carcinomata, and leaves no doubt that in this lies the explanation of the extraordinary range of cell forms, well known from human pathology and in the tar carcinomata of animals, which have been the subject of inconclusive controversy in the past.

Analogous experiments with undifferentiated mammary carcinoma of the mouse (alveolar carcinoma) have shown that here also complete loss of differentiation is not necessarily an irreversible process—an anaplasia in v. Hansemann's sense. When grown with an abundance of active connective tissue the large alveolar masses of polygonal cells become broken up into small trabeculae in which a minute lumen appears. A typical loose adenomatous structure, closely resembling developing mamma, results. The undifferentiated condition returns when the connective tissue is removed or suppressed by overgrowth of the carcinoma. From both series of experiments Drew concludes that the loss of differentiation, which has played so large a part in the theoretical discussion on cancer, is merely a superficial peculiarity of cancer cells when it occurs. Even when exhibited in its most superlative degree, it may be replaced by wonderfully perfect differentiation, without in any way affecting the essential malignancy of the cells, as evidenced by their behaviour on further culture or on inoculation into susceptible animals.

## A Hypothesis of Growth-activating Substances.

Another series of experiments has enabled Dr. Drew to gain an insight into the mechanism of repair and possibly the essential nature of the malignant transformation. It has been known for a long time that, while embryonic tissues and tumours grow with ease and without delay when placed in a suitable culture medium, adult tissues, even from young animals, only begin to proliferate after a considerable lapse of time. With adult kidney or heart of the rat this delay may extend to fourteen days. If, however, an extract of adult minced kidney, which has been incubated along with the fluid used for extraction for one or two hours, be added to the culture medium, growth commences at once in every case. If the extract of minced kidney be made with ice-cold saline without incubation, the initial delay in growth is as long as in the cultures made without it. When a similar ice-cold extract is made from a rapidly growing transplantable tumour, growth of adult tissue is elicited as energetically and with as little delay as when the incubated extract of minced kidney is used. At first sight this might be regarded as merely a consequence of the frequency of cell death and autolysis in new growths, but there is another possibility which should be borne in mind. It is that malignant cells produce, automatically and continuously, growth-activating substances, which normal tissues only elaborate in response to injury. The strength of the extract is directly proportional to the rate of growth of the tumour in the strains which have been investigated and not to the degree of necrosis. I incline to the opinion that the mode of production of these activating substances is an essential part of the difference between normal and cancerous cells.

This conception helps to rationalize the part played by chronic irritation in carcinogenesis. The specific irritants which are known to lead to the development of cancer are relatively mild, and do not cause rapid destruction. Rather, they may be imagined to set up a slight degree of protoplasmic disintegration still compatible with continued life of the cell. The curious sudden change after a long period of irritation, which marks the beginning of autonomous growth, would on this hypothesis correspond to a change in the protoplasm by which the production of activating substances turns from its purely induced reactive character to a self-acting process, as the result of a sort of education of the cells. Deelman has shown that this preparatory stage can be shortened by combining trauma (by scarification) with the application of the much more slowly acting tar products, and there can be little doubt in the light of Drew's experiments that such scarification produces activating substances in the damaged epithelium.

## Tar Carcinoma and Sarcoma.

My own experiments on the production of tar carcinoma have mainly been directed to overcome the refractoriness to cancer production—to which attention has already been drawn—encountered when animals which have already reacted with cancerous growth to tarring, or which have developed spontaneous mammary carcinoma, are painted with tar on an apparently healthy skin surface. A provisional account of this work will be presented to the cancer congress to be held in Strasbourg. So far tar carcinoma has not been produced in either group, and the conclusion is drawn that a generalized insusceptibility to the induction of primary cancer is present in animals which have once developed a malignant new growth. It is to be noted that

It excites the production of glucose out of the glycogen reserves. It is of use, therefore, only when these reserves are considerable, and should not be depended upon to antidote the symptoms of glucanemia in diabetic patients, because in them the glycogen stores are apt to be low. A similar relation between the percentage of blood sugar by Mann and Morgan had previously been described and convulsive symptoms in dogs deprived of the liver administration of glucose also removed the symptoms, other monosaccharides having only a slight effect.

There can be little doubt, then, that the symptoms are related to a lowering of the glucose tension in the tissues. But we cannot imagine that this, in itself, is responsible for the violent stimulation of the respiratory and muscular centers that evidently occurs. Some unphysiological condition must be developed as a result of the glucanemia, and it has been suggested that anoxemia may be an important factor. Omitted and Logan point out that there is a remarkable resemblance between an insulin convulsion and an asphyxial convulsion, and that the arterial blood is invariably intensely venous in colour when convulsions supervene. "It may possibly be that through the lowering of blood sugar certain oxidative processes become depressed to such a degree that the brain cells are affected in much the same manner as in asphyxia." "Whatever may be the nature of the toxic condition, it is clearly on the cells of the pons and medulla that it acts. It does not, like strychnine, act on the motor centres of the spinal cord, since insulin causes no convulsive symptoms in a decapitated cat, although it may lower the blood sugar to well below the convulsive level (Olmsted and Logan).

On what particular detail in the chemical structure of the molecule the remarkable specificity of glucose in antidoting the symptoms may depend cannot as yet be said, but it is evident that, by studying the relative antidoting value of various sugars and substituted sugars, we are furnished with an interesting method for determining the biological significance of the different side-chains and of the other molecular arrangements of the glucose molecule.

**THE PHARMACOLOGICAL ASSAY OF INSULIN.**  
The extent to which insulin lowers the blood sugar forms the basis for its pharmacological assay, one unit being originally defined by us as the amount which is required to lower to 0.045 per cent. within four hours in a rabbit weighing two kilograms and after twenty-four hours' fasting.

Since convulsions supervene at this level, their occurrence can be used as a check on the assay, and when small animals, such as mice, are used, so that large numbers can be injected with varying amounts of insulin, it can be made by observing the onset of the symptoms alone. In this case one mouse unit is defined by A. as the quantity of insulin which can cause convulsions in 50 per cent. of the animals within two hours, previous to being taken to maintain the body temperature and method of assay. Even when rabbits are carefully selected so as to correspond in weight and in every other particular, are similarly fed prior to the preliminary starvation period, and are injected intravenously, so as to obviate any uncertainties in rate of absorption, the occurrence of convulsions, do not always correspond. Differences in glycogen content, which can never be accurately adjusted by dieting, are probably largely responsible. We have attempted to circumvent these difficulties by continuing the observations on the blood sugar to the first half-hour after the insulin injections, hoping in this way to circumvent the influence of the glycogen reserves, but with no conspicuous success. Probably the most accurate method of assay is that worked out in Toronto by Dr. F. N. Allen on depancreatized dogs. The principle of this method, which was suggested by our clinical associates, is to determine the number of grams of glucose that a given quantity of insulin can cause to be metabolized so that there is no acid containing enough carbohydrate equivalent of insulin, as it is called, varies somewhat with the weight of the animal and the carbohydrate balance, but that it is satisfactorily constant when these conditions are made uniform. It is not likely that this method will succeed in the clinic, because of the varying degree to which different diabetic patients retain the power to produce insulin.

I have said enough about this problem of assay to indicate how difficult it is. It is probably advisable to point out, however, that it has been found advantageous to adopt, for clinical purposes, temporarily at least, a unit

Insulin also lowers the blood sugar in every known form of experimental hyperglycemia, whether this be produced by the addition of glucose exogenously or endogenously. With regard to the former type, Kadie has found that when insulin is injected into rabbits coincidentally with, or at varying periods preceding, the injection of sugar the curve of the resulting hyperglycemia becomes greatly altered. When the insulin injection coincides with that of sugar the curve rises to the same height as with sugar alone, but it returns much sooner to the normal level, and when the sugar is given some time after the insulin the curve is not only of shorter duration but is also much less in height. The maximal influence of insulin in suppressing the curve progressively rises again, the longer intervals the curves progressively rise again. At interval of about 75 to 90 minutes after the insulin. At pressing the curve is when the sugar is given at an interval in height. The maximal influence of insulin in suppressing the curve is in about eight hours. We have attempted to use these facts as the basis for a method of assay, but with no great success.

Of the endogenous forms of experimental hyperglycemia, we have studied the effect of insulin on those due to pigment, to epinephrin, to asphyxial conditions, and to anaesthetics, and Stewart and Hoggan have studied it on the peculiar form due to morphine. The hyperglycemia which becomes rapidly developed in glycogen-rich rabbits in all these conditions is greatly diminished, if not entirely absent, in animals injected with insulin, thus depending, obviously, on the amount injected. Most attention has been paid to epinephrin hyperglycemia, because in this case alone is it possible to control the intensity of the hyperglycemia by varying the dosage. This, it will be seen, offers a method for the assay of insulin, and Kadie has found that when equal quantities of epinephrin are injected into a series of uniformly fed rabbits along with varying quantities of insulin, there is usually a definite mathematical relation between the dose of insulin and the extent to which the blood sugar rises.

Further interest attaches to the antagonistic action between insulin and epinephrin, with regard to the blood sugar, because they are both hormones, although it is questionable whether the hormone action of epinephrin is of importance to the animal. It is significant in this connection that Stewart and Hoggan have found that the adrenalectomized than in normal animals, thus showing that the adrenals are in no way linked with the internal secretion of the pancreas in the control of sugar metabolism.

The observation that insulin can prevent the hyperglycemia due to ether is of clinical importance, because it is probably on account of this hyperglycemia that a large part of the risk of surgical operations on diabetic patients is due. It should be pointed out, however, that demonstrated by having the animal well under the effects of insulin before the ether is administered, than by giving insulin to animals that are already anaesthetized. This would seem to indicate that diabetic patients should be treated with insulin before being anaesthetized, and, indeed, that this preliminary treatment should extend over several days so that the reserves of glycogen may be augmented. I am informed by my clinical colleagues that insulin is of little avail in combating post-operative coma if its administration is delayed until after the operation.

An interesting antagonism between pituitrin and insulin has been described by Burn. Given in large doses, pituitrin, like insulin, may inhibit the hyperglycemia due to epinephrin or to normal animals, instead of there being a greater fall in blood sugar than insulin alone would produce, there

THE EFFECT OF INSULIN IN EXPERIMENTAL HYPERGLYCAEMIA.

HYPERGLYCAEMIA.

Mr. Pielou asked, on July 24th, whether instructions had been issued to ex-service Deputy Commissioners of Medical Services terminating their temporary services at the end of September; and that non-service doctors were being retained. Captain Craig replied that it had been found necessary to give notice of termination of employment to 36 out of the 83 Deputy Commissioners of Medical Services employed on a six-months' contract. Of those would then remain only 4 non-service officers and 6 not employed on a six-months' contract, and these medical officers were being retained in the interests of the pensioners because of their special experience and qualifications.

Mr. R. Morrison asked, on July 19th, for what reason the Ministry of Pensions refused to grant treatment allowances on the certificate of a man's panel doctor that the man was unable to work. Major Tryon said that treatment allowances were payable only when a medical officer of the Ministry was satisfied that the nature of an approved course of treatment was such as prevented a man from providing for his own support and that of his family. Full consideration was always given to any opinion expressed by the panel doctor on the requirements of any treatment and clinics recommending home treatment with allowances are not referred to a deputy commissioner of medical services in the ordinary way, but where the examination had been conducted by an outstation medical officer, his recommendation was referred to a deputy commissioner, who never disturbed a recommendation of allowances without personally seeing the man concerned unless the examining medical officer agreed, on reconsideration of the case, that allowances were not admissible.

On a question by Mr. Robert Jones, on July 19th, Major Tryon said that the Deputy Commissioner of Medical Services (Tuberculosis), Wales Region, was attached to the south-western region. The Minister had no definite knowledge whether this gentleman was acquainted with the Welsh language, but as he was performing his duties satisfactorily it might be assumed he had no difficulty in understanding and making himself understood by Welsh pensioners. During the year ended November, 1922, the Deputy Commissioner of Medical Services (Dental) for Wales examined personally 494 individual cases where dental treatment was provided; a considerable proportion had to be referred back for further treatment or adjustment. There were about sixty dentists on the pensions panel in Wales.

Major Tryon states that the final award of life pensions which have been granted up to date for each class of disease are as follows: Dysentery 67, enteric 19, malaria 293, trench fever 34, rheumatism 2,466, pulmonary tuberculosis 623, tuberculosis not pulmonary 265, affections of respiratory system 4,954, organic disease of heart 1,577, functional disease of heart 1,070, nephritis 553, gastric ulcer 146, appendicitis 59, other diseases of alimentary system 326, hernia 328, neurasthenia 2,234, epilepsy 333, tabes dorsalis 59, other organic nervous diseases 516, insanity 284, diseases of eye resulting in complete blindness 83, other diseases of eye 3,761, diseases of ear 3,743, debility 1,013, diabetes 22, flat foot 195, frost bite 907, gas poisoning 341, miscellaneous 5,078, diseases of veins 761, diseases of joints 1,136, and arterio-sclerosis 169. Total 33,445.

At present 2,976 men are undergoing treatment and training in convalescent centres. There was a waiting list of about 380, of whom 45 had been waiting more than two months; it was expected to provide for them within a fortnight. Any course of treatment necessary was provided for waiting cases.

In answer to Mr. Ede, on July 12th, Major Tryon said that the records of admissions to and discharges from ambulances, hospitals, or clearing stations during the war had now been sorted and indexed in one register. The work was begun by the War Office and completed by the statistical division of the Pensions Department as part of its regular duties.

During the past fifteen months about 2,800 claims for pension on account of tuberculosis have been accepted by the Pensions Ministry.

**Infant Mortality.**—Mr. Chamberlain said, in answer to Mr. A. V. Alexander, on July 9th, that as regards England and Wales no figures as to the deaths of illegitimate children of 1 to 2 years and 2 to 3 years of age were available prior to 1919. From this date the statistics were as under:

| Year. | Births. |               | Deaths under 1 Year. |               | Deaths, 1 to 2 Years. |               | Deaths, 1 to 3 Years. |               |
|-------|---------|---------------|----------------------|---------------|-----------------------|---------------|-----------------------|---------------|
|       | Total.  | Illegitimate. | Total.               | Illegitimate. | Total.                | Illegitimate. | Total.                | Illegitimate. |
| 1919  | 692,438 | 41,876        | 61,715               | 7,237         | 14,124                | 1,138         | 7,658                 | 469           |
| 1920  | 957,782 | 44,917        | 76,552               | 7,017         | 14,741                | 1,162         | 6,100                 | 364           |
| 1921  | 848,811 | 38,118        | 70,210               | 6,115         | 15,636                | 1,041         | 4,594                 | 336           |
| 1922  | 780,124 | 34,138        | 60,121               | 4,736         | 18,943                | 1,064         | 8,678                 | 453           |

**Trade Advertisements on Insurance Medical Certificates.**—Mr. Chamberlain, on July 18th, said that he did not think that any of National Health Insurance forms that bore advertisements were now being sent out from the Stationery Office. It was possible that Insurance Committees still had some stock on hand, but now printed by the Stationery Office. Captain Wallace asked, on July 23rd, when the contract for the Maypole butter advertisement on the back of the medical certificates under the National Health Insurance Act would expire; and whether the Minister of Health

would give an assurance that it would not be renewed. Mr. Chamberlain said that the contract for the advertisement on the back of Form Med. 40B related to a print of 20,000 copies of the form. A further supply of the form which had now been ordered from the Stationery Office would be printed without an advertisement.

**Milk Feeding Experiments.**—Mr. Hurd asked, on July 18th, whether the Minister of Health could state in general terms the results of the milk-feeding experiments among Birmingham Council school children, showing the physiological value of fresh milk as an article of diet and particularly the effect on children suffering from malnutrition of the addition to their dietary of a pint of fresh milk daily; and whether he would publish a report on the experiments to encourage co-operative movements of the same kind among other educational, agricultural, and health authorities. Mr. Chamberlain said it would not be possible in an answer to a question to state the results of the experiments even in general terms. The question of publishing a report was one for the authority responsible for the investigations. The Ministry of Health was conducting investigations in conjunction with the Medical Research Council into the nutritive properties of milk in the feeding of children and the question of issuing a report on these investigations would be considered.

**Institutional Treatment for Tuberculosis.**—Lord E. Percy said, on July 12th, in reply to Mr. T. Thomson, that the Ministry of Health approved generally of the arrangements made by the London County Council for the assessment of contributions payable by tuberculous persons towards the cost of institutional treatment provided by the Council. The statutes under which institutional treatment was provided in London for persons suffering from other infectious diseases did not authorize the recovery of any part of the cost of the treatment from the patient.

**Infant Welfare in Cumberland.**—Mr. Gavan Duffy, on July 12th, again by question asked the Ministry of Health to press upon the Cumberland Maternity and Child Welfare Committee the urgency of appointing qualified midwives to serve in the districts of Cleator, Cleator Moor, and Frizington. According to the medical officer of health, the infant mortality in the urban district of Cumberland last year was 116 per 1,000 as compared with 101 for Scotland, a rate which had been described as murderous. Lord E. Percy replied he was anxious to put the matter right, but the responsibility rested primarily with the local authority.

**The Lunacy Act.**—In answer to Mr. T. Griffiths, on July 12th, Mr. Chamberlain said the result of the inquiry made by the Board of Control showed that in only a very few institutions had the requirement of Section 8 of the Lunacy Act not been fully adhered to. The reference was as to informing patients in private asylums as to their rights of appeal. The Minister added that the Board had warned the authorities concerned and had received assurances that the Statute requirements would be fully observed.

**Royal Army Medical Corps.**—Mr. Becker asked, on July 24th, whether the Secretary for War would recommend that young medical men should be invited to serve in the Army Medical Service three, five, or seven years, with a gratuity at the end of the term, so as to maintain a steady flow of young men into the service. Lieut.-Colonel Guinness replied that it was already open to army medical officers to retire with gratuity after eight and a half years' service. He did not think that the shortening of this period was desirable or administratively practicable, having regard, for instance, to the requirements of the army in India.

**House of Commons Ventilation.**—A departure from reliance upon a scientific system of ventilation has lately been made in the House of Commons by opening some of the windows. This, on July 18th, gave rise to a variety of questions addressed to the First Commissioner of Works. Sir William Davidson inquired whether members were aware that for the first time they were breathing fresh air free from dead streptococci, and suggested that the windows on the other side of the Chamber should be open during divisions. Another member, Mr. Hardie, asked the Minister whether the pressure upon the outlets under the seats could be increased and whether the air inlet could be taken above the present terrace level. Sir John Baird said that he must await the result of experiments during the recess prior to forecasting any changes. Sir C. Kinloch-Cooke suggested that the Minister should visit the Stock Exchange and adopt the same principle at Westminster. Later Mr. Morrison called attention to a very strong odour of turpentine. The Speaker said that the First Commissioner would look into the matter.

#### Answers in Brief.

The number of convicted debtor and surety prisoners certified insane in prison during the last four years was 432. None of these persons died while still in prison. The Home Office had no information how many of them died before they were discharged from asylums. During the same four years 28 prisoners committed suicide in prison.

Lord Eustace Percy informed Dr. Chapple, on July 19th, that up to July 14th the number of applications received for registration under the Nurses' Registration Act was 4,436. After this date the Council had no power to accept applications by existing nurses.

Mr. Neville Chamberlain, in reply to Sir R. Newman, on July 23rd, gave the following figures of the death rate per million living from pernicious anaemia during the last three years: 1920, males 55, females 62; 1921, males 55, females 74; 1922, males 61, females 74. As regards ex-service men pensioned for injuries or disabilities, 152 out of a total of 60,000 deaths were due to pernicious anaemia.

almost at the doors of those who formerly had to travel miles in search of relief in sickness or accident. Some of the wards which had been closed from lack of funds were now being occupied by a class of patients who paid for the cost of their maintenance; other patients contributed according to their means. Nevertheless, although there was already accommodation for 400 beds, only 240 could be occupied at the present time, because the hospital had not enough income to maintain a larger number. The health of the Chairman was proposed in very warm terms by Dr. Ernest Barker, Principal of King's College, and the Duke of Connaught in his brief reply was able to announce that the appeal that evening had produced £6,000 towards the hospital funds.

## Correspondence.

### THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

SIR,—Dr. Wanklyn, in his note upon this subject (July 21st, p. 106), gives four main essential points for the differentiation of small-pox and chicken-pox. They are briefly—(1) distribution of rash, (2) degree of prostration, (3) depth of the lesions in the skin, (4) rate and manner of maturation of lesions. In regard to No. 2, "Degree of prostration," if Dr. Wanklyn could have added the experience recently afforded in Gloucestershire of "mild small-pox" to the wide experience which he reminds us he has had in the London area, he would almost certainly have shortened the four points to three, which only goes to prove that even when narrowed down to only four points it is still necessary to have an open mind, and that even in regard to all of these four points the statement can only be a general one which is more applicable to the formerly described type of small-pox than to the type now being experienced. The degree of prostration at any stage in many cases of mild small-pox stands at a cipher, and it cannot be less. I have watched contacts by close daily observation through the whole incubation period and early days of the eruption, without any prostration whatever being either complained of or discoverable, and at the same time have been seeing cases of quite typical chicken-pox where the prostration was marked. It is the difficulty at present at Gloucester to persuade people that their children have small-pox because there is no illness, and one of the doctors practising there told me last week that he had assured mothers that their children were not ill enough for the case to be chicken-pox, when they were being removed to hospital as suffering from small-pox.

Further, in regard to the other points mentioned by Dr. Wanklyn, numbers of cases have been seen that were undoubtedly small-pox, but in which all the signs were so trivial that not one of the four points mentioned above would apply. These were cases occurring in families some members of which had definite signs, whilst others occurring simultaneously had perhaps ten papules or less, sufficiently diagnostic when seen in connexion with the other cases, but which alone could not have been diagnosed by any manner of means.

All this, however, is not to say that Dr. Wanklyn's points, except the prostration, are not the chief points of diagnosis of small-pox, even when it is "mild small-pox."—I am, etc.,

July 21st.

J. H. GARRETT,  
M.O.H. Cheltenham.

SIR,—The importance and value of diagnostic signs in varicella cannot be over-estimated at any time, and never so much as now when chicken-pox and small-pox coexist. Many so-called distinguishing characteristics are quoted in textbooks, but all of these may fail, and leave one in perplexity. Others are more reliable, such as (a) the absence of lumbar pain, (b) the presence of one or more elliptical or oval vesicles, (c) the continued fever after the appearance of the eruption, (d) the fact that the vesicles collapse on being punctured in one place only, showing them to be unilocular.

But there are two signs which are pathognomonic, and, remarkable to say, seldom if ever referred to in textbooks, and which ought to have the first place assigned to them among differential diagnostic signs:

- (1) The early vesiculation and crusting of the papules, which may occur in so short a period as thirty-six hours.
- (2) The contemporaneous presence of papules, vesicles, and crusts on various parts of the body.

These two signs are invariably seen in varicella, and never observed in variola.—I am, etc.,

ALEX. THEODORE BRAND, M.D., C.M.  
Driffield, July 22nd.

### TREATMENT OF GONOCOCCAL INFECTION BY DIATHERMY.

SIR,—The article by Drs. Cumberbatch and Robinson in the JOURNAL of July 14th (p. 54) upon the treatment of gonorrhoeal rheumatism by diathermy is of great interest. The successful results of local attack upon the focus in the urethra and cervix are most encouraging, and the publication of their work in ampler form will be eagerly awaited. They seem, however, to look upon the matter from rather too narrow a view-point. Wilde has for many years maintained that the best treatment for chronic rheumatic affection is the raising of the body tissues a few degrees by hot packs or similar methods: if persisted in this line of treatment cures and not merely alleviates the condition. His views have not met with the recognition which they deserve: those who have adopted his line of treatment are convinced of its efficacy and it is very gratifying to find that the writers of this paper are able to lend support to his theory.—I am, etc.,

London, W., July 16th.

C. E. SUNDELL.

SIR,—I have read with great interest the valuable paper by Drs. E. P. Cumberbatch and C. A. Robinson published in the BRITISH MEDICAL JOURNAL (July 14th, p. 54) on the treatment of gonococcal infection by diathermy; it is specially interesting owing to the fact that cases of gonorrhoea both in men and women have been under treatment by diathermy for the past two years at the Derbyshire Royal Infirmary. The treatment has been carried out by Mr. A. K. MacLachlan, surgeon in charge of the Venereal Diseases Department, and myself. We can confirm the successful results obtained by Dr. Cumberbatch and his colleague.

The effect of diathermy on gonorrhoeal arthritis is immediately beneficial, and permanently beneficial. Treatment at the original seat of disease does undoubtedly cure gonorrhoea. I have already written on the diathermy technique adopted, and as soon as Mr. MacLachlan has completed his record of the cases a full statement will be published.

I think there is a distinct advantage for the electro-therapist to carry out these investigations in collaboration with one who has special knowledge of gonorrhoea, as the gonococcus is elusive, disappearing in smears for a considerable time, to turn up again when least expected. It would be a precarious decision for an electro-therapist to give a patient who has suffered from gonorrhoea a clean bill of health and permission to marry.—I am, etc.,

Derby, July 15th.

A. E. MILNER.

### BLOOD SUGAR ESTIMATIONS BY GENERAL PRACTITIONERS.

SIR,—I agree with Dr. Alex. J. W. Calder (July 14th, p. 85) that the tendency of some general practitioners to relegate new methods of diagnosis and treatment to specialists is regrettable. Undoubtedly some labour, time, and perseverance is required to master these new methods; but surely the general practitioner is as capable of taking pains to master a new technique as is his brother in the hospital ward or in the laboratory. The latter also is generally just as busy an individual as the general practitioner, so lack of time is hardly a valid excuse. Perhaps it is lack of fundamental knowledge that prevents the general practitioner from undertaking this work, but many general practitioners take additional qualifications such as D.P.H., etc., which require considerable knowledge of

FIG. 1.—Epithelioma contagiosum in pigeon (right-hand figure); normal control bird (left-hand figure). Section of epithelioma from this case is shown in Fig. 3.

FIG. 4.—Advancing edge of growth invading floor of mouth, showing epithelial downgrowths and swollen epithelium containing cell inclusions.

FIG. 3.—Section of nodule before degenerative new growth of epithelium; early stage before degeneration of cells has begun.

FIG. 5.—Low-power photomicrograph of epithelial growth advancing from buccal mucous membrane into the tissues forming the floor of the mouth.

FIG. 6.—Section of nodule from the nostril. Low-power magnification showing the characteristic epithelial downgrowths and islets of epithelium; a number of the latter show degenerative change in their centers.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, Mediscera, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### COTTAGE HOSPITALS.

DR. CHARLES H. GREENWOOD (7, Park Street, Ripon) asks for information as to cottage hospitals recently built or provided. If any such institution exists in Yorkshire the committee of the proposed hospital, which is to have two wards of eight or ten beds each, and an x-ray room, would like permission to visit it.

#### INJECTIONS OF ETHER IN WHOOPING-COUGH.

"M.R.C.S." asks for further information with reference to intramuscular injections of ether in whooping-cough, regarding which several references were recently published in the EPITOME (April 21st, 1923, paragraph 333; October 14th, 1922, paragraph 272; November 18th, 1922, paragraph 378). He inquires whether it is Ether Pur. (D.P.) which is used, and what, in the case of a girl aged 12 years, should be the dose and at what intervals.

#### INCOME TAX.

"W. F. W." bought an 8-h.p. B— in 1913 for £165, the usual price being £197. In 1920 he bought a 12-h.p. A— for £530 and agreed to sell the B— for £80, the cost of a similar new car being then £560; in fact, however the B— was retained and is used privately and, on occasions, for professional purposes also. The inspector refuses to allow more than £165—£80=£85.

So long as the B— remains available for professional use we are not clear that "W. F. W." has any claim to an allowance for the cost of replacing it. If, however, the inspector is prepared to waive that point, the allowance is determinable—on lines as to which official evidence was given before the Royal Commission on the Income Tax—according to the cost of replacement, and not, where that amount is less, according to the original cost of the machine. On this basis we compute the allowance as follows:

|                                              |     |     |     |     |     |        |
|----------------------------------------------|-----|-----|-----|-----|-----|--------|
| Original cost                                | ... | ... | ... | ... | ... | = £165 |
| Present equivalent for replacement purposes— |     |     |     |     |     |        |
| 15ths of £560                                | ... | ... | ... | ... | ... | = £470 |

### LETTERS, NOTES, ETC.

#### VACCINATION PROPAGANDA.

DR. WM. VERNER FURLONG (Dublin) writes: The method suggested by Dr. St. John Croley (July 21st, p. 120) is very good, but when one thinks that the actual disease—itsself passing through and killing a number of the inhabitants—has little, if any, effect in converting these antivaccination cranks, the only true remedy is compulsory vaccination. Why should the health and vitality of a people be at the mercy of ignorant faddists who cannot realize that vaccination is a means of adopting Nature's plan of immunity?

#### COOLIDGE TUBES.

DR. H. FLECKER (Melbourne, Victoria) writes with reference to the behaviour of the Coolidge tubes described by Dr. Robson in the JOURNAL of April 21st (p. 699): Surely this is to be traced to faulty operation of his outfit, particularly faulty rectification, rather than to any inherent faults of the tubes themselves. "I have myself," he continues, "noticed a steady diminution in

the lives of the new deep therapy Coolidge tubes, the first four of which last 190 and 130 hours at 5 milliamperes, and 80 and 48 hours at 6 milliamperes (200,000 volts). This I believe to be due to rectifier defect, and since it has been remedied I look forward to a much longer life with my next tube."

#### M. SPAHLINGER'S TREATMENT FOR TUBERCULOSIS.

THE *Manchester Guardian* last week published articles to which it gave great prominence detailing a proposal stated to have been made by the Lancashire Insurance Committee for establishing a tuberculosis institute at Eastbourne where insured persons from Lancashire could be treated with serum obtained from M. Spahlinger's laboratory near Geneva. This it was suggested could be done under Section 21 of the National Insurance Act, 1911, which authorizes an approved society or insurance committee "to grant such subscriptions or donations as it may think fit to hospitals, dispensaries, or other charitable institutions." The last term is wide, and has been interpreted to mean institutions of a similar kind to hospitals, or such other institutions as carry on work of the kind dealt with by the Act. A deputation from certain approved societies in Lancashire was in London last week, and after conferring with Lancashire members of Parliament and in their company it had an interview at the Ministry of Health with Sir Walter Kinnear, controller of the Insurance Department, and Sir George Newman, chief medical officer to the Ministry. The deputation, according to the *Manchester Guardian*, came away with the impression that "if certain technical difficulties could be overcome the scheme may receive the approval of the Ministry." We have already fully explained the position of the Ministry in an article published on May 12th, p. 330. The Ministry, through unofficial channels, has intimated to M. Spahlinger that it will be prepared to appoint a committee of recognized medical experts to watch the results of his method of treatment in a number of cases to be selected by a physician nominated by M. Spahlinger. One of the difficulties has been that M. Spahlinger declines to divulge the technique by which the vaccines and serums he makes are prepared, but the Ministry is prepared to waive any objection on this score. We believe that the Ministry's position is exactly what it has been during the last two or three years; that is to say, the Ministry is prepared, as soon as it can obtain some of the material prepared by M. Spahlinger, to have it tried on a number of suitable cases of his own selection, under the supervision of an impartial committee of competent and disinterested physicians. It is considered that the evidence hitherto received is not conclusive, although it is enough to call for further investigation. M. Spahlinger's methods imply nothing new in principle; they are essentially those which have been tried sometimes with and sometimes without success in other bacterial diseases. He seeks (1) to produce active immunity against the tubercle bacillus and its toxins in a patient by the injection of a vaccine, and (2) to make an antiserum which has antitoxic and bacteriolytic properties, and to use this to confer passive immunity on a human being. M. Spahlinger's vaccines are essentially similar to the tuberculin. He has, we understand, four vaccines made from tubercle bacilli, and a complete course of vaccine treatment consists of successive courses of injections of each of these four vaccines. The complete antiserum is made by mixing a large number of antisera each obtained from a horse which has been subjected to some particular course of injections; the serum of each such horse is called a partial antiserum. It is stated that M. Spahlinger and his family have provided about £80,000 to carry on his work, and the *Manchester Guardian* adds that he has recently received a contribution of £20,000 from an individual in this country. Whether the surplus funds from approved societies can be used to relieve M. Spahlinger's financial embarrassments is a legal question which we do not propose to discuss. It seems to us, as we have said before, that M. Spahlinger's difficulties are of his own making, and that they would disappear were he to accept the very reasonable and simple condition proposed by the Ministry of Health.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, 35, and 36 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 76.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No response for any such remittance not so safeguarded, be delivered, addressed to the Manager, 429, not later than the first post on Tuesday morning and, if not paid for at the time, should be made.

NOTE.—It is against the rules of the Post Office to receive *posto restant* letters addressed either in initials or numbers.

tively, operative collapse is the ideal treatment, cases of chronic fibrous phthisis with thick pleural deposits and rigid chest walls offering the best prospect. Operation should be done under local anaesthesia, since a general anaesthetic greatly increases the risk owing to loss of the cough reflex, thereby adding to the danger of aspiration of sputum and the greater tendency to exhaustion, and the procedure should only be undertaken after close observation and repeated consultation, and after compression by pneumothorax has failed. Two operations are advocated—Sauerbruch's total thoracoplasty, in which the chest is collapsed by resecting small portions of all the ribs at the costal angle through a paravertebral incision close to the spine, or partial pneumothorax with partial thoracoplasty, as indicated when stiff-walled cavities do not collapse or are maintained by firm pleural adhesions. Sauerbruch's operation can be performed under local anaesthesia, causes less shock than the Brauer-Friedrich's thoracoplasty, can be done in stages if necessary, and collapse occurs in two directions, transverse and sagittal, the chest wall falling in more and more as the ribs are resected from below upwards, while the resulting deformity is scarcely noticeable when the patient is clothed.

## Surgery.

72.

### Technique of Thoracic Surgery.

E. A. GRAHAM (*Journ. Amer. Med. Assoc.*, June 23rd, 1923, p. 1825) says that the avoidance of an open drainage during the acute pneumonic stage explains better than anything else the remarkable reduction of mortality in acute empyema; at Camp Lee the mortality dropped from more than 40 per cent. to less than 5 per cent. when early open drainage was given up. Intrathoracic operations can be performed on many patients, the author asserts, with a disregard of any form of apparatus for differential pressure; these are patients who have extensive adhesions or rigid mediastinal pleurae or those whose vital capacities are high; others will go through intrathoracic operations more safely if some auxiliary agent is present to assist in inflating the lungs if necessary. The author has found that Gwathmey's suggestion of using an ordinary nitrous oxide apparatus with a tightly fitting inhaler is satisfactory. He believes that the anaesthetic of choice in thoracic surgery is nitrous oxide and oxygen; at any time during the operation the lungs can then be inflated; also in children, even in cases of empyema, much of the fright and terror which accompany an operation under local anaesthesia can thus be avoided. In any event the surgeon should remember that too large an opening may cause death, and that the surest way to avoid fatal asphyxia is to close the opening by plugging it with lung, with gauze compresses, or in any other way. Surgical drainage is not necessary in all cases of acute lung abscess. Proper postural drainage and artificial pneumothorax in certain cases will give results just as satisfactory as surgical drainage. Postural drainage will be of value in those cases in which the abscess communicates with a bronchus. Artificial pneumothorax should, in the author's opinion, be reserved for small abscesses without adhesions. Surgical drainage should be employed in large acute abscesses, and probably in any abscess with increasing toxic symptoms. In chronic lung abscess surgical drainage with a tube is usually of little avail; in most of these cases the patient must be content with a life of chronic invalidism or submit to a radical surgical procedure.

73.

### Treatment of Haemorrhoids.

A. ALEXANDER (*Deut. med. Woch.*, June 15th, 1923, p. 792) is very favourably impressed by the treatment of haemorrhoids described in 1920 by Boas. After the intestines have been emptied and opium given, Bier's suction pump is applied once or oftener to draw out and distend the haemorrhoids. Perianal injections of novocain-suprarenin are given, and the suction pump is again applied. Into each haemorrhoid from 2 to 5 c.cm. (according to the size of the haemorrhoid) of a 95 per cent. solution of alcohol are injected. The author tried to modify Boas's technique by injecting the anaesthetic direct into the haemorrhoids, but this procedure frequently provoked severe gangrene of the haemorrhoids and was therefore discarded. After the alcohol has been introduced into the haemorrhoids they are pushed back into the rectum with the help of vaseline. If they are not completely pushed back they are apt to be nipped by the sphincter of the anus, and pain, lasting for less than a day, is followed by gangrene of the haemorrhoids. When they are completely replaced they are practically painless, and they may be felt fourteen to sixteen days later as small, firm nodules, of the size of a pea, above the sphincter. The patient should be kept in bed for three or four days after the injections without the bowels

being opened. At the end of this period plenty of vaseline should be introduced into the rectum to facilitate defaecation. The patient is usually confined to his bed for four or five days, and some are able to return to work at the end of this period. The author has adopted this treatment in 24 cases, in 22 of which a complete and permanent cure was effected at one sitting; in the other 2 cases the haemorrhoids recurred, their recurrence in one case being due to two minute haemorrhoids being overlooked on the first occasion. The use of Bier's suction pump helps to prevent small haemorrhoids being overlooked.

74.

### Fractures in Transplanted Bone.

S. L. HAAS (*Surg., Gyn., and Obstet.*, June, 1923, p. 749) points out that the success of an entire graft depends upon the ability of the cellular elements of the tissue to remain viable after the severance of its blood supply and retain its life properties until its vascular supply is re-established. In the bone graft it is believed that many of the osteoblastic cells survive and share in the regenerative processes. Others maintain that there is a complete degeneration of the cells of the transplant, and that all regenerative changes depend on secondary ingrowth from outside. It is important to know, in considering the healing of fractures in transplanted bone, if the cells of the transplant possess inherent power of repair. In order to obtain some information on these problems experiments were performed on dogs. First, an entire metacarpal bone was removed from the animal's foot. This was fractured and, after placing the fragments in apposition, was replaced in the foot. The entire blood supply was necessarily destroyed. Next a bone similarly located was transplanted in the muscles of the back. The fragments were thereby removed from any possible osseous contact. In a third group the fragments were boiled for ten minutes; and lastly, one fragment of bone was boiled and the other not injured to see if normal bone exerted any influence on the boiled dead half. These experiments showed that fractures in transplanted bone united firmly even when buried in muscle. Fractures in boiled transplanted bone showed no signs of proliferation or attempt at repair. Fractures in transplanted bone where half was boiled and half was alive united, even when buried in muscle. The author says that this test of the independent inherent osteogenetic power of the cells of transplanted bone established beyond doubt the proof of this independency.

### 75. Treatment of Acute Otitis Media in Children.

T. B. LAYTON (*Brit. Journ. Child. Dis.*, April-June, 1923, p. 65) points out that this treatment is one which should be carried out in nearly every case by the general practitioner, as the consulting specialist is seldom in the best position to apply it. The treatment must be both general and local. General treatment consists in keeping the patient at rest in bed, while local treatment consists in performing the operation of incision of the drumhead at the right moment. Layton maintains that it should be the aim of the practitioner never to allow a drumhead to rupture spontaneously, to look upon an inflamed ear which under his observation has gone on untouched to the stage of discharge as something of a disgrace to himself, just as he would consider to be so a case of acute appendicitis which in these circumstances had gone on to acute peritonitis. As it is important that nothing should prevent a good view of the drumhead being obtained, hot fomentations, which cause the superficial epithelium to swell up and entangle any bits of cerumen, should never be used, but pain should be relieved by applications of dry heat to the ear and side of the head with a hot-water bottle or pad of wool and by instillation of antiseptic drops. The drumhead should be incised as soon as it is seen to be bulged, the incision being made deliberately under a general anaesthetic. In the subsequent management of the case the practitioner must watch carefully for signs of mastoiditis.

### 76. Treatment of Fractures of the Lower End of the Humerus.

ALBERT MOUCHET (*Journ. de Méd.*, May 10th, 1923, p. 305) describes in detail the treatment for the different types of fracture of the lower end of the humerus met with in children. They are the most frequent form of fracture found in the region of the elbow-joint, and in diagnosing the condition x-ray examination is essential. In obtaining proper reduction a general anaesthetic is necessary, whilst care must be taken to look for lesions of the nerves round the elbow-joint. The usual type of fracture is where the lower fragment is drawn upwards and backwards by the triceps, and results from a fall on the hand with the elbow extended. In addition to the antero-posterior displacement there is often a lateral displacement, and this may be difficult to correct. Open operation may be required where there is a compound fracture or where the injury is complicated by damage to the vessels or nerves, and also where the fracture is otherwise

because at present there was no consensus of opinion on the matter and he thought it was highly important that some such consensus should be reached. In his preliminary remarks Mr. Bourne explained that he was combining his paper to the treatment of those forms of acute suppurative salpingitis which gave rise to the signs and symptoms of pelvic peritonitis. Clinically, such cases consisted essentially in an attack of acute suppurative pelvic peritonitis with a background of genital symptoms due to an acute suppurative of one or both Fallopian tubes. After briefly describing the cardinal signs and symptoms whereby this condition could be recognized, Mr. Bourne proceeded to outline the primary objects to be aimed at in treatment. The first object should be to arrest the acute disease and prevent its extension to the abdominal cavity proper. By efficient treatment it should be possible not only to localize the disease, but to cut short the long-drawn-out course of tubal and pelvic suppurative which nearly always occurred when expectant methods only were adopted. The second object should be to prevent the formation of chronic sequelae in the shape of adhesive pelvic peritonitis, interstitial salpingitis, pyosalpinx, etc. He considered that it was virtually impossible for a suppurative salpingo-peritonitis to resolve unless operated upon. Chronic thickening, adhesions and cold abscesses were the almost inevitable result producing a state of chronic semi-invalidity with relapses of acute symptoms and, in the case of bilateral infections, certain sterility. The third object should be to enable the affected tube to resolve sufficiently to resume its normal function. Their aim should be not only to prevent chronic ill health, but, if possible, to give back the reasonable hope of conception. Mr. Bourne proceeded to demonstrate with the assistance of slides the following general conclusions: (1) That in spite of the very acute inflammation the tubal epithelium was very resistant in the early stages and only desquamated in patches. (2) That after the acute phase had passed the greater portion of the epithelial surface was intact, but what lesions remained were very likely to develop adhesions. (3) That physical adhesions in the tube might be very extensive, cutting the channel into a number of diverticula which probably continued to harbour infection, and furthermore that it were relieved of its acute irritation at the earliest possible moment and that the barrier to the entrance of ova set up by the inevitably sealed abdominal ostium was relieved by artificial salpingostomy. As a rule the employment of expectant medical means would result in the acute symptoms passing off and the subsidence of any pelvic inflammatory mass, but the patient would probably be sterile and the slow development of chronic salpingo-oophoritis or pyosalpinx would only be a matter of time. Bourne urged strongly that this could only be attained by surgical measures, and claimed that operation should be undertaken at the earliest possible moment. After discussing of the principal objections to operation during the acute stage, Mr. Bourne proceeded to describe in detail the operative measures to be adopted according to the condition found on opening the abdomen. He advised the sitting up of both tubes: if the epithelium were found to be intact the tubes should be left, pelvic drainage being provided for either through the abdominal wound or by the vagina. By these means a check was given to spreading peritonitis and the formation of adhesions, the lumen of the tube was given a chance of resolution without the risk of further permanent changes caused by the continuation of suppurative, and the formation of a pyosalpinx was obviously impossible. If on laying open the tube the mucous membrane was so severely ulcerated and gangrenous as to be beyond the power of functional recovery it should be removed forthwith as a useless organ and probable source of future danger. Mr. Bourne had examined a recent specimen of a tube treated by salpingostomy in a patient who had died of intercurrent pneumonia and found that complete resolution had taken place. He claimed that if the tube were treated early salpingostomy

the first group would diminish; the essential requirement was a careful inquiry into the previous medical history. The key-note to the diagnosis was the condition of the caecum; if this were visibly distended, or if it were definitely felt to be hard and swollen under the fingers, then the obstruction was distal. In the most desperate cases of this group no attempt should be made to find the obstruction; but under local anaesthesia the caecum should be exposed through a right gridiron incision and "blind" caecostomy performed. By this means obstruction was relieved and the patient was rid quickly of the intense toxæmia, so that in a few days the operation, having for its object a search for the cause of the obstruction, could be proceeded with. He deprecated the performance of an exploratory laparotomy except in cases where very obviously the patient would not be likely to suffer. The experience in the Manchester Royal Infirmary over a period of years was that the percentage of mortality was nearly 50. He advocated strongly the routine performance of caecostomy, even in cases where secondary operations were performed; he felt convinced that those high figures could be very materially reduced. In cases where it was possible to make a more or less leisurely examination, exploratory laparotomy was likely to be the operation of choice. The discussion was taken part in by Mr. Seymour Barling (Birmingham), Mr. Mitchell (Belfast), Mr. Carson (London), Mr. P. Lockhart-Mummery (London), Mr. Charles Panaset (London), Mr. Geoffrey Grant (Cardiff), Mr. C. P. Child (Preston), Mr. Mothersole, and Mr. Lamourian (Ashton-under-Lyne). The general tendency of the discussion was altogether in support of Mr. Burgess's argument, but the hope was expressed that cases might in the future be received much earlier by the surgeon, as there must be many patients who suffered from slight colicky pains and diarrhoea of peristaltic nature, which on investigation proved to be the preliminary signs of a colonic cancer. If these early evidences were supported by x-ray and other examination the likelihood of acute obstruction occurring would be lessened. After a short interval the President vacated the chair, and Mr. Patrick (Glasgow) called upon Mr. H. J. Paterson (London) to read his paper on the question as to the improvement or otherwise in the results of operative treatment of malignant disease during the past twenty years. Mr. Paterson suggested that improvement was not so great in results as in technique, and he wondered whether the technique had not been carried beyond the pathological necessities of the case. He regarded it as questionable whether it might not be better to remove the infected glands at a later stage, on the ground that these glands were actually the first barrier of defence, and that it was unwise to remove that barrier at the primary operation. There were, he thought, good grounds for hoping for better results in the future, but these better results would follow rather upon earlier diagnosis than upon improved technique. Mr. Child expressed the opinion that there was a place for educating all people who came in contact with the sick poor—nurses, clergymen, and others—in the early signs of cancer; propaganda along these lines, which had for its object the education of the people, had been carried on in Portsmouth. The subject was further discussed by Sir Stclair Thomson, who contrasted the ideas of malignant disease of the larynx held by the great masters of present day, and pointed out that out of 60 cases of his own only 8 had shown recurrence within the first year. Mr. Major Greenwood spoke from the point of view of the statistician, and advocated a better standardization of operation statistics. Dr. Bruce (Toronto) said that in Canada as the direct result of propaganda the public were coming much more readily to consult the surgeons in regard to possible cancerous tumours.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Wednesday, July 25th.

The first meeting of this Section was devoted to a discussion of the treatment of acute salpingitis. In calling upon Mr. Aleck Bourne to read the opening paper, the President, Mr. Victor Bonney, said that this subject had been chosen

thinned out, even though the os is no wider than 2 or 3 cm., morphine, scopolamine, and time will almost always effect complete dilatation. If, on the other hand, the cervical rim remains thick and unyielding, the vagina should be plugged by the Dublin method, and morphine and scopolamine given—other methods of inducing dilatation are less effective and more dangerous. (3) When there is disproportion between the foetal head and the pelvis too much time must not be wasted on treatment of dystocia due to the soft parts; if there is not progressive advance after twelve hours of labour, Caesarean section must be seriously considered, and, since every dry labour is at least potentially infected, should consist, not in the classical operation, but in one that excludes peritoneal infection by peritoneal flaps.

## 82. Attempted Abortion and the Production of Monsters.

A. FEIL (*Paris méd.*, June 23rd, 1923, p. 559) states that the theory that attempted abortion plays a part in the production of foetal anomalies, finds considerable support in Dareste's experiments on hen's eggs. Dareste, improving on the somewhat primitive methods employed by Geoffroy Saint-Hilaire, and later by Prévost and Dumas, was able to produce a large number of malformations, such as spina bifida, single median eye, exencephalus, double heart, etc. The methods consisted in subjecting the eggs to a number of shocks or to unusual temperatures, or in applying a coat of varnish. Subsequently Kölliker discovered that an abnormal formation of vessels takes place and gives rise to malformation of the organs when the eggs are kept in an incubator deprived of air or one in which the air is not renewed often enough. Feré produced abnormalities by injecting various poisons into the eggs, such as morphine or lead salts, or by exposing the eggs to chloroform vapour, and Chabry was able to produce local malformations in ascidia at the site of injection. Mme Nageotte has recently described several suggestive cases of hemivertebrae and supernumerary ribs in which there appeared to be a relation between the malformation and the attempted abortion. Feil points out that though it would be illogical to attach too much importance to attempted abortion in the production of foetal anomalies, inasmuch as tuberculous and syphilitic play a very important part in their causation, cases of malformation may undoubtedly occur in a previously normal family where attempted abortion is very likely responsible. The possibility of this factor should therefore be realized by the medical profession and impressed upon the public.

## 83. Treatment of Uterine Prolapse in the Aged.

ACCORDING TO H. HARTMANN (*Gynecol. et Obstét.*, 1923, vii, 5, p. 415), treatment of prolapse by the formation of an artificial vaginal septum, although generally abandoned, has a useful, if strictly limited, application in aged patients, to whom capacity for coitus is of no importance. As practised by Le Fort and Neugebauer, operation was followed by speedy recurrence, but, in common with Cotte and Creyssel, Hartmann has had satisfactory results from the following technique: long and wide rectangular strips of mucous membrane, reaching from the cervix to the urinary meatus and the fourchette respectively, are excised from the anterior and posterior vaginal walls, and the raw surfaces are united by a series of absorbable sutures, of which the first are inserted near the cervix, and the successive ones more remotely. The operation is easy, rapid, and free from danger, and can be done under local anaesthesia.

## Pathology.

### 84. Toxins of *B. dysenteriae* Shiga.

MCCARTNEY and OLITSKY (*Journ. Exper. Med.*, June, 1923, p. 767) have succeeded by a new method in separating the exo- and endo-toxins of Shiga's dysentery bacillus. The exotoxin is an early product of the growth of this micro-organism *in vitro*, is relatively heat-labile, and yields an anti-exotoxigenic immune serum. The endotoxin is a product of the autolysis, or disintegration, of the bacillus, with the resultant liberation of intracellular components, is heat-stable, and is not neutralized by anti-exotoxigenic serum. The exotoxin has a specific affinity for the central nervous system in the rabbit; the endotoxin, on the other hand, affects only the intestinal tract. The pure neurotoxic exotoxin can be obtained from the filtrate of early growths of Shiga bacilli before bacterial disintegration commences. The endotoxin, which arises later as a result of bacterial dissolution, is always admixed with the exotoxin, which is first produced in the medium, and therefore the toxins require mechanical separation for purification. McCartney and Olitsky succeeded in obtaining the endotoxin alone by suppressing the exotoxigenic function of Shiga bacilli by growing the micro-organisms

under anaerobic conditions, either in fluid medium under a petrolatum seal or in this medium in an anaerobic jar. The bacteria, now in an exotoxin-free environment, could be autolyzed, or dissolved, with the resultant liberation of intracellular components, including endotoxin. This pure endotoxin had a special affinity for the intestinal tract, producing oedema, haemorrhages, necroses, and ulcerations, but did not affect the central nervous system. They studied also the diffusion of the toxins through such as collodion sacs, and showed that bacilli implanted intra-abdominally:

depending on the permeability of the collodion membrane; highly permeable sacs allowed the early passage of exotoxin, somewhat denser membranes permitted only the diffusion of substances inducing agglutinins or immunity. Cultures in sacs placed in flasks yielded in the fluid surrounding the membrane first exotoxin and later endotoxin, and the passage through the membrane of endotoxin depended on the rate of bacterial disintegration within the sac. Thus the biological and physical differences of the two toxins, which had already been demonstrated, were confirmed.

### 85. The Mechanism of Haemoclastic Shock.

THE phenomenon of haemoclastic shock has hitherto been held by most writers to be an indication of hepatic insufficiency, but F. MOUTIER and J. RACHET (*C. R. Soc. de Biologie*, June 16th, 1923, p. 151) now bring evidence to suggest that it is really no more than a result of variation in vago-sympathetic tone. The experiments on which this conclusion rests consist in a comparison of the effects produced on the same individual of the administration of milk and of distilled water. On a fasting stomach the individual to be tested was given 250 c.cm. of fresh milk; then after an interval of some days the same experience was repeated, with the substitution of an equal quantity of distilled water for the milk. Before each test, and ten minutes and thirty minutes after, the blood pressure was taken and a leucocyte count performed. In 9 out of 10 subjects examined parallel results were obtained, 5 giving a haemoclastic shock and 4 showing the inverse phenomenon—increased blood pressure and a rise in the number of white cells. In the remaining subject ingestion of water determined a haemoclastic shock, ingestion of milk the reverse phenomenon. On a further series of 5 subjects a triple test was performed, using fresh milk, powdered milk, and distilled water. The results of the fresh milk and of the water coincided every time, whereas those given by the dried milk agreed in 2 cases and disagreed in 3 cases. From these experiments the authors feel justified in regarding the phenomenon of haemoclasia as the effect of a physical disturbance of the vasomotor system rather than of a chemical reaction connected with the liver.

### 86. Amato "Bodies" in Scarlatina.

IN 1913 Amato described certain "bodies" found with the leucocytes in the blood of scarlatina patients and not in other diseased conditions. TRON (*Lo Sperimentale*, An. 76, 1922, p. 5) has examined the question in relation to 40 cases of scarlatina, 14 cases of measles, 3 cases of serum rash, 1 case of varicella, and 3 healthy controls. He finds that Amato "bodies" are almost always present in the very earliest days of the disease. The number is usually greater when the fever is well marked, and diminishes with the defervescence, disappearing as a rule before the temperature falls. In relapses the "bodies" reappear. The number of "bodies" and their presence in the circulation does not seem to have any relation to complications. The clinical importance of these "bodies" lies in the help they may give in early diagnosis of doubtful cases. Of the 14 cases of measles examined 13 gave a negative result and 1 showed a few scarce "bodies." In the other non-scarlatinal cases the results were negative.

### 87. Classification of Types of *B. pertussis*.

M. HAYANO (*Japan Medical World*, May 15th, 1923, p. 104) describes four types of *B. pertussis* which he was able to differentiate by means of agglutination tests. Strains of each type were examined by rabbit serums immunized by intratype venous injection of type cultures. The classification was upheld clinically when diagnostic tests for pertussis were applied to the serum of patients. In all cases the serum reacted for a certain type, two of which appeared more virulent than the others, and it was also demonstrated that a predominant type existed in different epidemics. Autogenic and polyvalent vaccines gave good results in treatment of the disease (out of 159 cases satisfactory effects being obtained 94.8 per cent.), and a number of experiments demonstrated the possibility of successful prophylaxis by vaccine. The dose administered for treatment was 200 increasing to 400 millions, seven or eight subcutaneous injections proving efficient.

wanted to emphasize the value of the typical stance described by Dr. Cameron, and compared it to the post-war posture of the modern young woman. She had notes of 40 cases, of which 20 had a bad stance; in the majority of cases this tended to get well. She commented on the memory of many young children, and also on the desire to conquer, which in some cases might take unpleasant shapes. Dr. W. A. Potts (Birmingham) wished to stress the importance of a very thorough physical examination, which should include as far as possible the function of the endocrine glands, for in some cases excellent results were obtained by small doses of thyroid gland. A lack of good parental control was most injurious to the child; example was the best form of psychotherapy. Parents should remember their own childhood and not interfere with the child's development by excessive anxiety. Sensation should be studiously avoided. Every child should have some simple religious instruction, and also instruction in the elementary facts of reproduction from its mother.

Dr. Critchton Miller (London) was sorry that Dr. Cameron had not gone further into the question of the etiology. He suggested that a faulty calcium metabolism might produce other effects than mere skeletal deformities. But physical inferiority was not always a mark of the nervous child. Faults of parental control could produce bad results even in a perfect physical specimen. A fundamental point in treatment was, as he expressed it, to "switch off the lightning," for in many cases the child showed a "glory" in his misdeeds. He mentioned especially nocturnal enuresis as a symptom for which archaic forms of treatment still persisted. It was the supreme symptom of infantility and the life of the cradle, and was often used as a defence against unpleasant realities such as school. Sir Robert Armstrong-Jones (London) congratulated the Section in that the subject had been so ably treated by a general physician, as well as by psychiatrists. He recalled the pedagogic maxim of "Don't say don't," and emphasized the value of making the child feel its own responsibility. He should be encouraged to see what was the importance of sleep had been hardly adequately emphasized, and such nervous children should be made to rest for twelve hours out of the twenty-four. In conclusion he would point out the threefold parts of the child—physical, mental, and spiritual—all of which must receive proper attention and study. Dr. R. G. Gordon discussed the psychological causes of the various special symptoms such as suggestibility which had been brought forward by Dr. Cameron. The personality was formed by the interaction of the inborn dispositions and of the environment. Many nervous children were backward, and a few were mental defectives. A neurological basis, especially disease of the frontal lobes, must not be forgotten. Dr. Hartford disclaimed the occurrence of squints in nervous children, and the connection between squints, left-handedness, and stammering. He spoke favourably of psychotherapy, especially of carefully guided auto-suggestion. Mr. Luman was called on by the President to give the meeting an account of his work on squints in children, and he gave an interesting summary of his conclusions on the connection between left-handedness, squints, and stammering.

Dr. Perry (Brighton) thought that the nervous child was more common now than twenty years ago, especially amongst the Jewish people. He was strongly opposed to the treatment of these cases by psycho-analysis. Dr. Peter Macdonald wished to draw the attention of the Section to the work of Alexander in the formation of the correct posture for man, and described the good effects which he had personally experienced from his method of treatment. Dr. Cameron briefly replied to the points raised in the discussion.

SECTION OF OPHTHALMOLOGY.

Thursday, July 26th.

The President of the Section, Sir John H. Parsons, said it was his privilege to welcome a satisfactory attendance of members and visitors to the Section, and to express the gratitude of them all to their colleagues of Portsmouth.

An interesting programme had been provided for them. Mr. Ransom Pickard of Exeter, Vice-President of the Section, thereon took the chair, and called upon Mr. A. H. H. Sinclair of Edinburgh to introduce the subject for discussion—the clinical significance of scotometry. Mr. Ransom Pickard (Exeter) demonstrated charts showing the variations in infantile mortality since 1841, and the relationship of these factors were likely to be permanent or temporary. Dr. Wheatley exhibited charts showing the variations in infantile mortality in the general death rate had been continuous, but that since then the fall had been large and continuous. The fall in the general death rate had been continuous, though comparatively small during the sixty years previous to the fall in the infant rate. He suggested that the factors death rate had been neutralized in the case of infant—improved sanitation, etc.—which had reduced the general mortality by other opposing factors. These he found in an increased prosperity among the working classes without increased education or improvement in a sense of responsibility. In these circumstances increased prosperity was a danger to infant life as it tended to increase drinking and to reduce the amount of breast-feeding. The effect of the Education Act was seen, as would be expected, in a reduced mortality in the generation following its passing. An analysis of replies to inquiries received from the medical officers of health of forty-four towns showed that twenty-five attributed the reduction to health visiting and child

The Section was opened by the President, Dr. McNamee, Thursday, July 26th.

difficulty in delineating relative conditions. Nevertheless, there would always be standardized tests; in reply, agreed with the desirability of the use of field, tension, and size of cups in the discs. Mr. Sinclair, Ransom Pickard (Exeter) demonstrated charts correlating that there was much to be learned concerning them. Mr. Ransom Pickard (Exeter) demonstrated charts correlating some of the physiological aspects of these tests, and remarked that there was much to be learned concerning them. Mr. Ransom Pickard (Exeter) demonstrated charts correlating some of the physiological aspects of these tests, and remarked that there was much to be learned concerning them. Mr. Ransom Pickard (Exeter) demonstrated charts correlating some of the physiological aspects of these tests, and remarked that there was much to be learned concerning them.

with trypsin in alkaline reaction was found to remove its hypoglycaemic action, which was not the case when faintly acid extract was incubated without trypsin. Similarly prepared extracts of spleen and liver had no effect, neither had otherwise active extracts of pancreas when given by mouth or by rectum.

These results, confirmed many times, seemed sufficient to prove the existence of the elusive pancreatic hormone, and the next problem was to devise a method by which it could be extracted from pancreas obtained from the abattoirs. As a step to this, Banting and Best took advantage of the fact, established by Ibrahim, that up to four months of foetal life in the ox the pancreas does not contain active proteolytic enzyme, although there is evidence, furnished by the experiments of Carlson and Drennan, that the antidiabetic hormone is produced by the gland during foetal life. They found that active extracts could be prepared from the pancreas of the foetal calf, and they carried the search with success to adult pancreas, using alcohol, as had previously been suggested by E. L. Scott and Zuelzer, as the extraction fluid, in the hope that in this medium proteolytic destruction of the hormone would not take place. Larger quantities of extract being now available, they succeeded in keeping a depancreated dog more or less constantly under the influence of the extract for a period of over two months, during which the animal gained in weight and exhibited only in slight degree the characteristic general symptoms of diabetes.

The criticism has been made that Banting and Best's experiment in which simple extracts of duct-ligated pancreas were used formed no essential step in the investigations which have given us insulin. I need scarcely reply to these criticisms. They were apparently made without any appreciation of the real obstacle that stood in the way of development of the subject—namely, convincing evidence that an antidiabetic hormone does actually exist in the pancreas—and to Banting and Best is due the credit of furnishing this by experiments of a different type from those of their predecessors. We owe much to the initiative, skill, and patience they displayed in completing this first essential step in the investigation.

It now became apparent that attempts should be made to see whether the crude alcoholic extracts of ox pancreas could be sufficiently freed from those substances which made them unsuitable for subcutaneous administration to diabetic patients, either because of local irritation or general toxic effects. At this stage of the investigation we were joined by J. B. Collip, who, in a remarkably short time, succeeded in isolating from the alcoholic extracts, by fractional precipitation with alcohol, a precipitate which contained the antidiabetic hormone in high concentration, and which, in watery solution, could be injected subcutaneously in man without any deleterious effects. At the same time it was also discovered that the blood sugar is lowered in normal rabbits by subcutaneous injection of extracts containing the antidiabetic hormone, and to this observation was due in large part the rapid progress which it was possible to make in the isolation of insulin. It offered a ready means for testing the relative potency of the various precipitates and filtrates, and of determining the most favourable conditions under which extraction of the gland should be carried out.

Provided with a comparatively simple method for the preparation of insulin, it now became possible to undertake a systematic investigation of its physiological and chemical properties and its possible therapeutic value, and I shall endeavour to describe briefly what has been found, and to indicate, in a general way, what appear to be the most hopeful lines for further research. It seemed advisable at this stage to group the problems demanding immediate investigation, and this was done as follows:

1. The effect of insulin on the respiratory exchange, the distribution of glycogen, and the metabolism of fat in animals rendered diabetic by pancreatectomy.
2. Its therapeutic effect in diabetes mellitus.
3. Its effect on the blood sugar of normal animals and the symptoms which result from overdosage.
4. Its pharmacological assay.
5. Its effect on the blood sugar in the various forms of experimental hyperglycaemia.

6. The physiological mechanism by which it lowers the blood sugar.

7. Its source.

8. Its chemical reactions and its preparation on a large scale.

In planning the investigations of these problems we were in the fortunate position of having the whole-hearted collaboration of several trained workers, not only in my own department (E. C. Noble, J. Hepburn, and J. K. Litchford), but also in that of internal medicine under the direction of Professor Duncan Graham (W. R. Campbell and A. A. Fletcher). We were also afforded, by the Connaught antitoxin laboratories of the University under the direction of Professors J. G. Fitzgerald and R. J. Defries, the facilities necessary for the preparation of the extracts on a large scale, and through the generous support of the University and the Carnegie Corporation it was made possible later to add several others to the group of workers.

#### THE EFFECT OF INSULIN ON THE METABOLISM OF CARBOHYDRATES AND FATS IN EXPERIMENTAL PANCREATIC DIABETES.

From the time carbohydrates are absorbed, mainly as glucose, into the blood of the portal circulation until they are completely oxidized, changes in chemical structure are constantly occurring. These consist, partly, in a condensation of several glucose molecules to form glycogen, and partly in a splitting of the molecule, proceeding through various intermediate stages. The intermediary substances formed at each stage are doubtless in a certain state of equilibrium, one with another. Many of them do not accumulate sufficiently to be detectable by chemical means, being changed into the next stage almost as quickly as they are produced, and at the present time we are limited, in our attempts to follow the various steps in the process, to observations on the concentration of glucose in the blood, the amount of glycogen deposited in the tissues, and the type of combustion occurring in the organism as a whole. In diabetes marked and significant alterations occur in each of these; the blood sugar rises to a high level, glycogen practically disappears from the liver and becomes decreased in the muscles—except the heart, in which it increases—and the nature of the combustion process, as revealed by the behaviour of the respiratory quotient, becomes changed so as to indicate that no carbohydrate is being oxidized. It is safe to assume that the increase in blood sugar is secondary to the other changes, but it is difficult in the present state of knowledge to understand the relation. It has been a favourite hypothesis that the primary fault in diabetes is in the oxidation of glucose, or in the chemical changes which precede, and that this leads to the drafting to the tissues from the glycogen reserves of a plethora of sugar; a sort of forced-feeding process, as it were. Another hypothesis is that the glucose molecule must become altered in some way before it can be either oxidized or condensed into glycogen, and that this alteration does not occur in diabetes. Through the work of Irvine and his school much light has been thrown in recent years on the structure of the sugar molecule, and it has been shown that besides the well known  $\alpha$  and  $\beta$  varieties of glucose, in which the oxygen linkage is between the first and fourth carbon atoms, there is also a third variety, called  $\gamma$  glucose, in which the oxygen ring is displaced from the normal stable position. The detection of the  $\gamma$  sugars depends mainly on a comparison of the reducing and polarizing powers of the solutions, and, by using this method, Winter and Smith have recently published results which they interpret as showing that the alteration in the glucose molecule alluded to above is the production of  $\gamma$  glucose. According to this view,  $\gamma$  glucose is a necessary preliminary stage in the oxidation of glucose, and, if we suppose that it is also so for its condensation into glycogen, the interrelation of the three changes found in diabetes becomes immediately intelligible.

I have dwelt on these theoretical considerations because of their great interest in connexion with the mechanism of the action of insulin. For it is a significant fact that this hormone, when administered to depancreated animals, completely restores to normal each of the three functions. We have repeatedly found, for example, that when it is

line; some of the quantitative cases were familial, some toxic, and some due to depression or elevation of sensibility. He mentioned the relation between Paget's disease and nerve deafness, and gave notes of a case. He dwelt upon the importance of the lowering of the upper tone limit, and of the use of the monochord in diagnosing nerve deafness. He described cases of astounding acuity of hearing in the blind and in certain types of neurasthenics, where whistlers could be heard round several corners. Perhaps the canals were getting less valuable to man. Mr. J. J. Wright (British) classified 71 cases from the point of view of etiology; those with an obvious cause, such as trauma and syphilis, offered no difficulty. Of the remainder, two-thirds were females. In these doubtful cases seric foot accounted for a certain number, some were functional, and in these one could find a history of some suggestion at the outset. Of the remainder, child-birth, thyroid deficiency, and vasomotor rhinitis accounted for the majority. Sir James Dundas-Grant (London) discussed senile deafness, vertigo (which in middle-aged was caused mechanically), the value of guanine in unilateral labyrinthine vertigo, tuning-fork tests, war cases, transmutations, deaf-mutism, and numerous other points. Mr. Leighton (Manchester) said syphilis was not to be overlooked, emphasizing the psychological factor, described a labyrinthine storm relieved by inflation, and mentioned the importance of caloric tests. The President said the speeches had brought out the important point that in a large proportion of cases of internal ear deafness evidence of middle-ear disease was present. Many cases of so-called nerve deafness were possibly due to disease in the foremen rotundum. It was important that all cases of hyperostosis of the meatus showed signs of deafness of the internal ear type. He had not found during three years with the army any chronic deafness caused by quinine or by malaria.

Mr. E. D. Davis (London) read a forty-nine page paper on retrobulbar neuritis of nasal origin. He and most of the speakers agreed in finding it a sufficiently rare disease. Out of 54 cases in only 4 could he prove the existence of sinusitis. Sir Stclair Thomson (London) condemned a tendency in some countries to operate upon sinuses without evidence of disease, simply because improvement had followed such operations. They must draw the line somewhere. Dr. Ritchie Rodger and Mr. Somerville Hastings, on the other hand, had seen dramatic improvement after opening sinuses apparently healthy. Mr. H. D. Gillies (London) read a too short paper upon the treatment of deformities of the nose, with special reference to the nose of certain syphilitis. The treatment rested upon a diagnosis in terms of the structures lost by the disease; a two-stage operation was necessary—the first to restore the lining, and the second the cartilage. Previous failures had been due to an omission in regard to the lining.

**SECTION OF RADIOLOGY AND ELECTROLOGY.**  
*Wednesday, July 25th.*

In the Section of Radiology and Electrology, which was presided over by Dr. S. Gilbert Scott, a discussion took place on the x-ray examination of the urinary tract. The discussion was opened by Dr. R. W. A. Salmon, who pointed out the enormous advances in urology in respect to more accurate diagnosis which had taken place since the advent of x rays. The success of x-ray examination of the urinary tract might be said to depend on two main factors—namely, proper technique and accurate interpretation. The latter could only be obtained by combining the experience of the radiologist with that of the urologist. The speaker proceeded to give a detailed account of the most suitable x-ray apparatus, the preparation of the patient, the technique of exposure, and the routine of examination. He considered that radiology of the urinary tract was of considerable value, not only because stones could be seen, especially the larger kidney and bladder stones, but chiefly because the relative movement of a supposed stone shadow to that of the kidney and its direction of movement with respiration could be determined.

The President, Sir Percy Bassett-Smith, opened the first morning's session with a general outline of the day's programme. Group Captain M. W. Black then read his paper on "Some considerations in the estimation of physical efficiency." In the discussion which followed Surgeon Commander R. Digby Bell asked whether in doing what was the best method of measuring abdominal breathing exercises holding of the breath was essential, and not appear to injure a man to hold his breath up to a minute. The speaker replied that in his experience it did not appear to injure a man to hold his breath up to a minute. The speaker discussed the period of circulatory discomfort, but as a practice for educational gymnastics it was not to be encouraged. He agreed that abdominal breathing was hard to measure; callipers appeared to be the best means, and measurements were taken at the level of the tenth rib. Lieutenant-Colonel G. R. Sylvester-Bradley, R.A.M.C., read a précis of his paper on some aspects of normality, with special reference to the selection of recruits. He asked whether in examining candidates all possible precautions were taken to put them at their ease, owing to the increase in pulse-rate which the excitement of examination aroused. Group Captain Black replied that all allowances were made for unnecessary technical details.

**SECTION OF NAVAL AND MILITARY HYGIENE.**  
*Wednesday, July 25th.*

The President, Sir Percy Bassett-Smith, opened the first morning's session with a general outline of the day's programme. Group Captain M. W. Black then read his paper on "Some considerations in the estimation of physical efficiency." In the discussion which followed Surgeon Commander R. Digby Bell asked whether in doing what was the best method of measuring abdominal breathing exercises holding of the breath was essential, and not appear to injure a man to hold his breath up to a minute. The speaker replied that in his experience it did not appear to injure a man to hold his breath up to a minute. The speaker discussed the period of circulatory discomfort, but as a practice for educational gymnastics it was not to be encouraged. He agreed that abdominal breathing was hard to measure; callipers appeared to be the best means, and measurements were taken at the level of the tenth rib. Lieutenant-Colonel G. R. Sylvester-Bradley, R.A.M.C., read a précis of his paper on some aspects of normality, with special reference to the selection of recruits. He asked whether in examining candidates all possible precautions were taken to put them at their ease, owing to the increase in pulse-rate which the excitement of examination aroused. Group Captain Black replied that all allowances were made for unnecessary technical details.

The President, Sir Percy Bassett-Smith, opened the first morning's session with a general outline of the day's programme. Group Captain M. W. Black then read his paper on "Some considerations in the estimation of physical efficiency." In the discussion which followed Surgeon Commander R. Digby Bell asked whether in doing what was the best method of measuring abdominal breathing exercises holding of the breath was essential, and not appear to injure a man to hold his breath up to a minute. The speaker replied that in his experience it did not appear to injure a man to hold his breath up to a minute. The speaker discussed the period of circulatory discomfort, but as a practice for educational gymnastics it was not to be encouraged. He agreed that abdominal breathing was hard to measure; callipers appeared to be the best means, and measurements were taken at the level of the tenth rib. Lieutenant-Colonel G. R. Sylvester-Bradley, R.A.M.C., read a précis of his paper on some aspects of normality, with special reference to the selection of recruits. He asked whether in examining candidates all possible precautions were taken to put them at their ease, owing to the increase in pulse-rate which the excitement of examination aroused. Group Captain Black replied that all allowances were made for unnecessary technical details.

upsets the metabolic balance and thereby induces an abnormal state. In the diabetic, on the other hand, the injection of insulin only restores to the body a hitherto missing part of the metabolic machinery and enables it to run smoothly again.

Within a few minutes of the intravenous or subcutaneous injection of a moderate dose of insulin, the percentage of sugar in the blood begins to fall, and it continues to fall, more or less in a straight line, for a period which varies from about half an hour to several hours, according to the animal; afterwards the curve may gradually become less steep or it may begin to rise again.

The prompt onset and the steep nature of the fall in blood sugar are characteristic features of the action of insulin, and are quite unlike the hypoglycaemic effects that may be produced by administration of other substances, such as phosphorus or the insulin-like materials that have been prepared by Collip and others from clams and from various vegetable sources. Indeed, the character of initial fall is such as to give the impression that the process responsible for it must be one operating within the blood itself—an intravascular glycolysis. But this cannot be the case, since we have been unable to find that the addition of insulin to defibrinated blood kept under sterile conditions at body temperature outside the body has any influence on the rate at which sugar disappears; neither is there any difference in this regard between the blood of normal animals and that of animals injected with insulin at varying periods preceding the withdrawal of the blood. Evidently, therefore, the locus of action of insulin is extravascular; it is in the tissue cells. We must conclude that the insulin sets up some process by which, as it were, a vacuum for sugar becomes established in these cells, so that sugar is removed from the blood. One may imagine that in the tissues there exists a certain balance between the concentration of free glucose, the complex carbohydrates from which it may be derived, and the various derivatives into which it breaks down prior to its oxidation. In other words, one may speak of a certain tension of glucose as being necessary in the tissues and consider the action of insulin as having the effect of reducing this tension so that glucose diffuses into them from the blood in order to maintain it.

After about half an hour the blood sugar in the rabbit usually begins to rise again, or at least the fall to become much less pronounced, indicating that the effect of insulin is becoming neutralized by the liberation of sufficient glucose from the glycogen stores of the muscles and liver. This, of course, means that the hypoglycaemia following insulin will be much more prolonged and will ultimately become much more pronounced in animals provided with small reserves of glycogen than in those that are rich in glycogen. Such can readily be shown to be the case, and it is significant that a well fed animal may withstand many times the dose of insulin that would prove fatal to one that was starved.

It is customary to imagine that the glycogenic mechanism of the liver is so finely attuned to respond to the concentration of sugar in the blood that glycogenolysis immediately sets in when this falls below the normal level. That such is not the case following insulin may depend on the fact that the glycogen, which is first of all called upon to maintain the glucose tension in the tissues, is that of the muscles themselves; but I will not here venture further into the various interesting consequences of such an hypothesis. It is at least significant that the glycogen of the muscles, as well as of the liver, is usually reduced in animals that have been given large doses of insulin (McCormack and O'Brien and Dale and Dudley). On account of its practical significance it should be pointed out that it is because of the poverty of the glycogen reserves that the blood sugar of diabetic patients treated with insulin is more apt to fall suddenly to a dangerously low level than in normal persons.

#### THE HYPOGLYCAEMIC SYMPTOMS.

When the percentage of blood sugar has fallen to about 0.045, curious symptoms supervene. They were first observed in rabbits, and in a typical case consist of a violent convulsive seizure in which the animal throws itself over sideways, usually first in one direction, then in the other,

with the head retracted and the hind limbs in an extended position.

The condition is not unlike that caused by strychnine or by acute asphyxia, except that certain groups of muscles are less affected by the convulsions than others. After a period, usually of from 30 to 60 seconds, the convulsions cease and the animal lies on its side in an unconscious state, with rapid, shallow breathing, and perhaps showing running-like movements of the extremities. The exact condition of the animal at this stage may, however, vary considerably; well fed and therefore glycogen-rich animals often sit in apparently normal fashion between the convulsive seizures, which are often brought on by attempts to move. After a varying period the comatose stage is followed by another convulsive seizure, and these phases may continue alternately for an hour or more, the convulsions becoming feebler and feebler and the rectal temperature falling, until at last the animal dies of respiratory failure. After death rigor mortis sets in at once. The arterial blood is venous in colour and clots very quickly. Preceding the onset of typical convulsions there are usually premonitory symptoms of hyperexcitability and evidence of hunger; sometimes, however, paralysis of the extremities is the first symptom.

The symptoms vary somewhat in other animals. In the dog the first signs are usually very rapid breathing, restlessness, and general hypersensitivity; muscular twitching then becomes evident and the sphincters may relax. Barking is often a prominent symptom, and there may be frothing at the mouth. At this stage, or as the first symptom, convulsions not unlike those seen in the rabbit may supervene, and between them the animal lies on its side, showing violent twitching of the musculature, almost a tetany. It is evidently unconscious. The rates of breathing and of the pulse increase; inspiration is usually short and jerky, and inspiratory tetanus not infrequent, so that artificial respiration may have to be applied. Attempts to get on its feet often cause convulsive seizures, and, during recovery, the muscles of the extremities, particularly the anterior, are seen to have entirely lost their power of co-ordinate action. In etherized dogs even massive doses of insulin have no immediate effect on the blood pressure.

In the cat the symptoms are like those in the dog, profuse salivation, mewing, and relaxation of the sphincters being especially marked.

In the mouse kept at room temperature, A. Krogh observed that insulin may only cause the animal to become weak, but its temperature falls to a very low level. If it be kept in an incubator at about 28° C., however, characteristic symptoms supervene—convulsions and coma, preceded by paralysis of the legs—with doses of insulin, which, when compared on a body-weight basis, are only about one-fifth that necessary for rabbits.

This influence of body temperature is particularly interesting, since it probably explains the apparent immunity of frogs even to massive doses of insulin. We failed to note any symptoms even in three days after injecting insulin, but A. Krogh has since found that they occur in a day or so later—a fact which we have confirmed.

In man, in whom the subjective symptoms can be interpreted and cardio-vascular changes more accurately observed, the picture is different. When the blood sugar reaches about 0.075 per cent. the patient experiences extreme hunger and a sense of fatigue. He usually becomes anxious and may lose his emotional control. Actual tremor of the musculature is rarely seen, but there is a definite sense of tremulousness and some inco-ordination for fine movements. "Vasomotor phenomena are common; pallor or flushing, sometimes one after the other; a sense of heat, of chilliness, almost always a profuse sweat" (Banting, Campbell, and Fletcher). At lower levels of blood sugar, acute mental distress, mental disturbances, delirium, and finally coma, with loss of the deep reflexes, supervene.

The correspondence between the onset of definite objective symptoms and a blood sugar percentage of 0.045 in laboratory animals is remarkable. Sometimes, as in starved animals receiving a large dose of insulin, the blood sugar may be found to be considerably below this level when convulsions first appear. Very occasionally it is decidedly higher, and immediately after a convulsion the sugar may rise somewhat. These facts suggest that the symptoms are the result of the lowering of the tension of glucose in the tissue cells below a certain critical level—a condition of "glucatonia," we may call it—to which the hypoglycaemia runs parallel. This view is supported by the striking manner in which the symptoms are almost instantly removed by administration of glucose, and it is of great significance that other hexose monosaccharides have only a slight beneficial effect, although of course their injection causes a marked rise in the reducing power of the blood. Mannose and laevulose seem to be somewhat more efficient than galactose. None of the pentoses or disaccharides has any effect. Injection of epinephrin, subcutaneously, also removes the symptoms, no doubt because

should first be given. He thought it unwise to refuse to operate because there was a possibility of adhesions being present. He maintained that the ordinary physical signs were more important than x-ray evidence. If a case was deemed suitable for thoracoplasty this operation should not be delayed too long. Mr. Burrell said that unilateral artificial pneumothorax should be done earlier than was the practice; there was less likelihood of finding adhesions in early cases. Mr. Tudor Edwards referred to shock after thoracoplasty. In cases where the blood pressure had been taken before and after operation there was no actual fall in systolic pressure if the operation was performed under local anaesthesia. He preferred to do the operation in two stages, as most of the cases which he got were at a late stage of disease.

#### SECTION OF ORTHOPAEDICS. Friday, July 27th.

The Section of Orthopaedics held its session on July 27th, with Mr. T. H. Openshaw, the President, in the chair. Among those present during the morning was Sir William Maclewan. The proceedings commenced with a discussion of the present attitude of orthopaedists towards the subject. Mr. P. Jenner Verall, secretary of the Section, announced that by agreement those who had promised to speak had each been requested to confine their remarks to particular parts of the subject. He then gave a short account of certain less drastic procedures. Mr. Harry Platt described the methods he employed for hip cases. Mr. McCrae Aitken spoke of manipulative measures and minor open operations, osteo-arthritis of the hip. Mr. Rowley Bristol spoke also on hip cases, emphasizing the fact that it was constant pain which provided the clearest indication for operation. He also referred to the problem of double severe knee conditions in this disease, and the factor of spasmodic reduction in the production of pain in the hip. Sir Robert Jones spoke of the value of manipulation, especially in adducted hips and the shock of large operations, and advised his well known operation for osteo-arthritis hips in old persons. Mr. Elmslie then replied briefly. Mr. E. Laming Evans read a highly scientific and interesting paper on acute rickets in late childhood and adolescence, and showed interesting slides. The subject was discussed by Mr. Elmslie. Mr. Robert Milne gave a valuable communication on the prognosis of Legg's disease of the hip, illustrated by numerous slides. The subject proved to be highly controversial; Messrs. Aitken, Platt, Elmslie, and the President took part in the discussion, no very definite consensus of opinion being reached. Mr. P. Bernard Roth spoke on the treatment of fractures of the lower end of the humerus. The subject was discussed by the President. Mr. Naughton Dunn read a paper on congenital talipes equinovarus, its prognosis and treatment, emphasizing the importance of early and complete manipulation and prolonged fixation, and insisted that in bad cases open operation should not be delayed unduly. The President discussed Mr. Naughton Dunn's paper, and went on to read a short paper on some deformities of the os calcis, in which he gave a valuable description of fractures of the os calcis and indicated the methods he employed in treating these and other deformities.

#### SECTION OF VENEREAL DISEASES. Friday, July 27th.

At the meeting of the Venereal Diseases Section held on July 27th, with the President, Sir Archibald Reid, in the chair, the subjects under discussion were the prevention and treatment of chronic gonococcal prostatitis and rickets. The opening papers being read by Mr. Kenneth Walker (London) and Dr. David Watson (Glasgow). Mr. Kenneth Walker, in introducing the subject of chronic

prostatitis, laid stress on the frequency with which the prostate and vesicles furnished the gate by which organisms entered the blood stream. As a rule vesiculitis and prostaticitis were associated conditions and the fact that the vesicle was a horizontally placed structure lying along its long axis made it difficult to differentiate a prostaticitis from a vesiculitis, so that mistakes in diagnosis might arise. However, as the treatment of the two conditions was in the main the same this was not of great importance. He then went on to discuss certain points in treatment, in particular prostatic massage, electric massage of the prostate, and diathermy, vaccines, and sulfarsol. In Mr. Kenneth Walker's opinion a definite reason was taking place against the excessive use of instruments, particularly in posterior lesions, where they were more than likely to damage the tissues and perpetuate the disease. Dr. David Watson then discussed the prevention and treatment of vesiculitis. He said that vesiculitis was a rare disease and that there was very little field for the extensive operative measures advocated by certain American urologists. Vaccines had not proved of much use, at any rate in the later stages of the disease. The whole success of treatment in gonorrhoea lay in avoiding secondary infections and such complications as vesiculitis and epididymitis. Mr. David Lees (Edinburgh) continued the discussion and agreed that such treatment as vaccine therapy and the injections of sulfarsol were of use in the earlier rather than the later stages of the disease. Mr. Campbell (Portsmouth) divided cases of chronic prostaticitis and vesiculitis into two types—those in which the lesion was associated with no symptoms and no metastatic troubles, and those associated with symptoms and such secondary complications as intitis. Vaccines were useful in the latter rather than in the former type. Another form of treatment that he had found of use was the application of heat to the prostate by rectal irrigation. Surgeon Commander Parnall agreed that vesiculitis was a rare disease and stated that he had abandoned all vaccines except the detoxified variety. However, by the use of the latter the average duration of complicated cases at Haver had been reduced from 70 to 46 days. Dr. Hudson (Newcastle) spoke of the danger of using too strong antiseptics for larvae, and Dr. Eames (London) defended the position of the pathologists and claimed that many failures in vaccine therapy were due to failure to incorporate in the vaccine all the organisms and all the strains of gonococci that were responsible for the discharge. After the readers of the opening papers had replied, Sir Archibald Reid congratulated the Section on the excellent discussion that had taken place.

#### SECTION OF ANAESTHETICS. Thursday, July 26th.

A well attended meeting of the Anaesthetics Section was held on Thursday, July 26th, at the Municipal College, Portsmouth, under the presidency of Dr. W. J. Essery. In declaring the meeting open the President, after expressing his regret at the enforced absence of the London Secretary, Dr. H. R. Phillips, through an accident, extended a warm welcome to his colleagues from other centres. He then called upon Dr. Harold Sington (London) to read his paper on anaesthetics for children. Dr. Sington first considered the preparation of a patient before the anaesthetic, and drew special attention to the importance of examining the urine completely in every case. Owing to its great importance he considered anaesthetics in some detail. He next discussed the choice of an anaesthetic, mentioning that the Great Ormond Street Hospital staff were convinced that for children ether preceded by a hypodermic injection of atropine would always be the anaesthetic of choice. The operation for which gas and oxygen was peculiarly well suited was that for hypertrophic stenosis of the pylorus; ethyl chloride was very useful for dental extractions in childhood. Dr. Sington next discussed various practical points in the administration of an anaesthetic to a child, and concluded with some suggestions for making the recovery as free from discomfort as possible. The paper led to a lively

is little change, or, it may be, a rise. A dose of pituitrin which in itself has little effect on blood sugar is thus capable of neutralizing the hypoglycaemic action of insulin. This observation has been confirmed by Logan and Olmsted, who have also found that it is necessary to give enormous amounts of insulin to cause any decided decrease in the hyperglycaemia which is present in decerebrate cats still retaining the pituitary gland. When this gland is absent, on the other hand, not only is the hyperglycaemia much less pronounced, as Bazett had suggested it would be, but insulin promptly lowers the blood sugar and hyperglycaemic convulsions can readily be induced.

All of the forms of experimental hyperglycaemia just alluded to are primarily due to a rapid breakdown of the glycogen of the liver, and that produced by epinephrin may therefore be taken as a type. This does not, of course, warrant the assumption that some have made, that a hypersecretion of this hormone is the underlying cause of the hyperglycaemia in the other forms. Indeed, Stewart and Rogoff have conclusively shown that such is not the case, with the possible exception of that caused by morphine. Taking epinephrin hyperglycaemia as a type, then, it seemed of interest to compare the amount of glycogen left in the livers of uniformly well fed rabbits after they had been given equal doses of epinephrin, some of them at the same time also receiving insulin. This observation, made by E. C. Noble, has shown very definitely that the insulin protects the glycogen against breakdown. In one experiment, lasting eight hours, the livers of two animals receiving epinephrin alone contained 1.40 and 1.96 per cent. of glycogen, whereas those of three others which were given insulin along with the same amounts of epinephrin contained 8.12, 6.4, and 3.64 per cent. of glycogen. It is of interest to note that it was necessary to give about forty times the usual dose of insulin to cause convulsions under these conditions, and that sometimes the convulsions occurred while there was still over 10 per cent. of glycogen remaining in the liver. The results show quite clearly that insulin antidotes the glycogenolytic action of epinephrin.

#### THE PHYSIOLOGICAL MECHANISM BY WHICH INSULIN LOWERS THE BLOOD SUGAR.

We are now arrived at a stage where it will be advantageous to consider briefly the possible mechanism of the hypoglycaemic action of insulin. We have presented evidence that this is not because it stimulates increased glycolysis within the blood itself, and have concluded that insulin in some way lowers the tension of glucose in the tissue cells.

Further evidence that insulin causes the sugar to pass from the circulating fluid into the tissues more quickly than normal has been furnished by perfusion experiments on the isolated mammalian heart.

Hepburn and Litchford, using Locke's method, found, as previous workers have, that an average of 0.9 mg. of glucose per gram of (rabbit) heart per hour disappears from the perfusion fluid. By adding insulin to the perfusion fluid the average sugar consumption rose to over 3.0 mg., and in some cases reached the value of over 4.0 mg., the highest without insulin being below 2 mg. They did not find that insulin affected the heart beat, nor could they detect any significant differences in the glycogen content of the hearts used in the two groups of experiments.

Hoping to be able to demonstrate a similar effect of insulin on the sugar content of fluid perfused through skeletal muscles, these workers attempted to perfuse the hind limbs of various laboratory mammals, but, although every possible precaution was taken to avoid interruption of the circulation prior to starting the perfusion, or a fall in temperature, they could never succeed in preventing either marked oedema or vaso-constriction. This failure led them to compare the sugar concentration of blood removed at the same time from the femoral artery and vein, and from the portal vein, of anaesthetized or decerebrate animals, and to see whether insulin would cause the differences normally existing between these bloods to become changed. It was found not to do so. McCormack has since found that this method is also incapable of revealing an increased retention of glucose as a result of insulin, either in the muscles or in the liver of depancreated animals, in which, as we have seen, insulin certainly causes glycogen to be formed. This shows that the method is not sufficiently sensitive for the purpose for which it was employed.

The evidence of the observations on glycolysis and the perfused heart leave little doubt, however, that the glucose is lost in the tissue cells, and the problem narrows itself down to the cause for its disappearance. The possibilities

that may be considered are: its polymerization into glycogen, its oxidation, and its reduction to substances similar to fatty acids.

With regard to its possible conversion into glycogen, the fact that insulin causes large amounts of this polysaccharide to become deposited in the liver of depancreated animals when carbohydrates are given would seem at first sight to lend support. But the conditions, as already pointed out, are fundamentally different in the normal organism. As a matter of fact, it has been shown that insulin given to normal rabbits, instead of causing glycogen to be deposited, has the opposite effect, and either prevents the deposition of glycogen when it is given along with carbohydrates to previously starved animals (McCormack and O'Brien) or causes the stores of this substance to become reduced when given to well fed animals (Dale and Dudley).

Further evidence that insulin does not stimulate formation of glycogen in normal animals has been obtained by Noble by perfusion experiments on the liver of the turtle. When each of the two lobes is perfused for several hours with Ringer's solution containing glucose, under exactly similar conditions except that the fluid on one side contains insulin, the relative amounts of glycogen in the two lobes were found to be the same as they usually are. Since the normal variation may be considerable, the method is not a very delicate one, and on this account Noble has also used that of observing the sugar content of the perfusion fluid, as recommended by Snyder, Martin, and Levin. By comparing this for equal periods of time, with and without the addition of insulin, no differences could be detected. The only objection to the experiment is that insulin may not act quickly enough in the case of cold-blooded animals to make it possible in the time of perfusion for measurable quantities of glycogen to be deposited.

Clearly, therefore, none of the disappearance of sugar from the blood of normal animals which follows the injection of insulin can be accounted for by its polymerization to glycogen. Why, then, does insulin cause glycogen to be deposited in the diabetic animal, and why does it inhibit the breakdown of glycogen in experimental hyperglycaemia? The reply, based on the considerations already set forth, is that an excess of insulin, beyond that actually required for the control of carbohydrate metabolism, develops towards glycogen an action which is the reverse of that which it has under normal conditions. When insulin is given to the diabetic animal, on the other hand, it supplies a previously missing agency necessary for the oxidation and polymerization of glucose. To explain the retarding effect which insulin has on glycogen breakdown in experimental hyperglycaemia, we may suppose that the sugar which is produced by this process is a mixture of active and inactive forms, and that insulin, by tending to produce the former in relative excess, disturbs the balance existing between the sugars and glycogen, so that less glycogen is broken down. This suggestion assumes some sort of balanced action between glycogen and its hydrolytic products, for which, however, there is no experimental evidence.

The possibility that glucose disappears because excess of insulin causes its oxidation to be increased has been investigated by observing the respiratory exchange.

In the experiments of Dixon, Eadie, and Pember, dogs and rabbits were used. In the former, the results show that insulin causes a very marked increase in oxygen consumption and in respiratory volume and rate, but very little change in the respiratory quotient. These changes do not, however, begin to be evident until from 30 to 60 minutes after giving the insulin, by which time the blood sugar has completed its initial fall and stands at about 0.060 per cent., which indicates that the sudden call for sugar on the part of the tissue cells cannot be attributed to its increased oxidative breakdown. There can be little doubt that the increased metabolism is dependent upon the hyperexcitability and the increased muscular tone of the animal. It reaches its acme when convulsions supervene, and it develops either steadily or intermittently. Evidently, as the tension of glucose declines, conditions become established within the nerve centres which excite them and which may be dependent upon an intracellular lack of oxygen. That the development of the symptoms depends on the lowering of the glucose tension is supported by the observation that their severity is lessened by the injection of glucose.

In rabbits, in which it will be recalled increased muscular tone is not so marked a symptom as in dogs, the increase in oxygen consumption does not set in until the convulsions occur—indeed, there is often, if not usually, a drop both in this and in respiratory volume. Sometimes in rabbits the respiratory quotient rises decidedly. It would be rash at this stage to draw definite conclusions from these results, but it is quite plain that the initial fall in blood sugar, which is primarily what we must attempt to explain, is not due to any increased combustion of glucose.

The remaining possibility that glucose is reduced to substances related to the fatty acids receives some support in certain of the observations from the behaviour of the respiratory quotient. This may rise to over unity without

Winter and Smith. The insulin prepared from these sources appears to differ from that prepared from pancreas, in that its action in lowering the blood sugar is delayed, sometimes for a day or so, which is also the case with an insulin-like substance prepared by Collip from various vegetable sources, and styled by him, in recognition of these differences, "glucokinin." Best and Scott have also succeeded in preparing insulin, or insulin-like substances, from various other sources. It would appear, therefore, that the distribution of hormones capable of accelerating the disappearance of glucose from the blood is widespread, not only in the animal kingdom but in the vegetable as well; it is probable, however, that these do not all have the same physiological action. In the investigation of this we must bear in mind that many substances have been known for long to be capable of lowering the blood sugar—for example, peptone, hydrazin, certain mineral salts, phloridzin, etc. All of these also cause glycogen to disappear from the liver, and indeed certain of them cause structural changes in this organ. Although it would certainly be desirable to have substances like glucokinin having a more prolonged action than insulin in depressing the blood sugar, we must exercise some caution in recommending them for clinical use until it is certain that they have no deleterious effects on the liver. It is possible also that these substances merely stimulate the secretion of insulin from the pancreas of the animal into which they are injected, or serve as precursors for its production. If such be the case, then they can have little value in diabetes.

I have endeavoured in this review to adhere strictly to ascertained facts, and have refrained from venturing to speculate with regard to the numerous problems in metabolism, both of animals and plants, for the investigation of which insulin may prove a useful instrument. If I have succeeded in giving a bird's-eye view, as it were, of the results that have been obtained, I shall consider that my efforts have not been in vain, and I shall feel repaid if, as an outcome, others join us in the work on insulin.

## THE RELATION OF FAULTY NUTRITION TO THE DEVELOPMENT OF THE EPITHELIOMA CONTAGIOSUM OF FOWLS.

(With Special Plate.)

BY

ROBERT McCARRISON, M.D., D.Sc., F.R.C.P.,  
LIEUT.-COLONEL, INDIAN MEDICAL SERVICE,

IN CHARGE OF THE DEFICIENCY DISEASES INQUIRY, INDIAN RESEARCH  
FUND ASSOCIATION; PASTEUR INSTITUTE, COONOR.

EPITHELIOMA CONTAGIOSUM (avian variola; fowl-pox; chicken-pox; epitheliosis; pigeon-pox; canker) is a disease of birds which has been described as follows:

It is characterized by "the appearance of wart-like nodules, varying in size to that of a pea, or slightly larger, on those parts of the skin of the head where feathers are few or absent, such as the nostrils, openings of the ears, the comb, wattles, and the eyelids, the last named being one of the most common sites. The nodules are encapsuled, firm in consistence, with a caseous centre, and usually remain discrete, but a number situated closely together form a mulberry-like mass. In some cases the contents resemble fatty tissue, except for being more vascular; in others they are warty and contain flakes of coagulated material very much like small clots of milk. Lesions are also found on the buccal mucous membrane, the affected parts of which become covered with thick whitish-yellow exudate, in appearance resembling that of diphtheritic false membrane."<sup>1</sup>

"Marx and Sticker, in 1902, demonstrated that the disease was due to a virus which was capable of passing through a Berkefeld filter, and their results were confirmed by Juliusberg and Hertzog. Burnet, however, obtained very varying results in his filtration experiments. He found that the virus was frequently arrested by the Berkefeld filter, although the infective material had been largely diluted with water. It has not been possible to cultivate the virus artificially, and its nature remains a matter for further investigation. It exists in the blood, internal organs, and in the fluids expressed from the lesions, and is possessed of considerable

resistance to the action of heat\* and antiseptics. The disease can be transmitted by rubbing juice from the lesions into an area of skin from which the feathers have been removed, or which has been lightly scarified, and the lesions then produced are confined to the part inoculated. According to Burnet, it can also be transmitted by intravenous inoculation and by feeding, and the lesions develop at the predilection seats of the disease."<sup>1</sup>

"The microscopic examination of the epithelioma of the skin shows, according to Polowinkin, the epithelial layers thickened and the epithelial papillae elongated inward; in the papillary layer the vessels are dilated and, like those of the subcutis, surrounded by migrating leucocytes; in addition there are small haemorrhages into the tissue of the papillary layer. Cell-inclusions are found in the swollen epithelium, similar to Guarneri's pox-bodies (Loewenthal, Burnet). In a general way the characteristic features of the efflorescences are composed of a more or less pronounced hyperplasia and proliferation of the cell elements of the skin, which sooner or later succumb to degeneration. This is associated with the extension of the process to the external skin and there follows a condition which, according to Reischauer, is similar to true pox; the difference lies mainly in the fact that in bird-pox the more chronic character of the disease causes the nodular and tumour formation to predominate."<sup>2</sup>

My purpose here is to record the occurrence of epithelioma contagiosum in pigeons under conditions which indicate that nutritional factors may play an important part in its development. The observations have another and a more general interest, inasmuch as they tend to show that a certain state of faulty nutrition, and of deranged metabolism, favours the entry into the body and the activity of an invisible virus possessing the specific property of inducing epithelial new growth.

## Experiment.

Polyneuritis columbarum was produced in a number of pigeons by exclusive feeding on washed milled rice. Twelve of them were "cured" at the height of the disease by artificial feeding with green *mung dal*. Within forty-eight hours of the disappearance of polyneuritic symptoms they were placed in an open-air pen with sixty healthy stock birds, and had access to the mixture of grains found to be most suitable, in this climate and at this altitude, as a stock food for pigeons. It consists of one part of green *mung dal*, one part of *ragi*, and four parts of *cholum*. Thus, the birds, after the cure of the polyneuritis, received a food containing a sufficiency of vitamins and other essentials for their maintenance in perfect health. Owing to their poorer nutrition when put into the stock-pen, they were less able to protect themselves against attack by their more lusty companions. The lessened ability to escape injury and to recover from it is an important effect of faulty food on the animal organism, and in this instance abrasions about the head—the most frequent seat of injury—appear to have favoured the entry of the virus of epithelioma contagiosum. In general, then, the twelve "cured" birds were more subject to injury than their fellows. Nevertheless, as weeks passed they appeared to prosper; their plumage improved and their body weight rose. Six weeks to three months after they were put into the stock-pen seven out of the twelve developed epithelioma contagiosum (Fig. 1), while their sixty healthy well fed companions remained free from it.

The growths occurred about the angles of the mouth, on the eyelid, the nostril, in the neighbourhood of the ear, and in the floor of the mouth beneath the buccal mucous membrane (Fig. 1). Their histological characters are shown in the photomicrographs (Figs. 3 to 6). The epithelial downgrowths stimulated in appearance those seen in such a condition as carcinoma of the penis in man. The epithelial new growth was infiltrative to a limited extent, had local destructive properties, and its cells tended to undergo rapid degeneration.

The nodules were emulsified, and the emulsion was rubbed into lightly scarified surfaces at the angle of the mouth of six healthy and well-fed pigeons. In two of these diphtheritic false membranes developed, and one of them died from the extension of the false membrane backwards, resulting in interference with swallowing and in involvement of the air passages; the second recovered. The other four were unaffected. In none did the inoculation of the emulsified nodules cause infiltrative new growth of epithelium. It would seem, therefore, that these well nourished birds were resistant to the influence of the growth-inducing virus, since those affected by its inoculation exhibited only superficial lesions. It appears likely that the virulence of the virus was not great; it was great enough to cause typical lesions in birds whose nutrition was faulty, but not so great as to be capable of causing infiltrative lesions in healthy, well-nourished birds.

\*In this respect resembling the growth-promoting substance evolved during the process of autolysis of tissue cells.<sup>1</sup>

INTERNATIONAL CONGRESS OF

SURGERY.

SERO-THERAPY AND VACCINO-THERAPY IN

(Continued from page 117)

In the absence of Major Parker Hitchins of Washington, Dr. Alcieter (Nancy) opened the discussion by reading the paper of Dr. Bay of Paris. Although knowledge of the general action of serums and of vaccines, and of their part in specific effects in such a phenomenon as Vidal's colloidal shock, was important in modern surgery, they would not be able to make full use of the resources offered by sero-therapy and vaccine-therapy unless they reached to the full value of specificity. Immunity and specificity were inseparable terms, and they could not confer real and durable immunity without specific intervention. Apart from tetanic and antitoxic effect, such as anti-serums having an especially antitoxic effect, serums used in surgery were uncertain in their effect, at least as regards general infection. It was therefore advisable to draw attention to local applications of sero-therapy and to point out that injections of serum were less and less productive of effects as they were repeated. They should be reserved for cases of extreme need and used as a last resort. The use of vaccines was to produce in the organism a state similar to the condition it would be in if there had been a natural attack of the illness in question. This went to show that in surgery vaccination could not be claimed to produce any practical results, because surgical infections, when healed, did not confer immunity. Vaccine-therapy was chiefly used, and this consisted of the treatment of an illness during the stages of its development by means of the germ, more or less artificially modified, of the illness. Another method was to try to get a mixed immunization by a concurrent use of serums and vaccines, which they might call "sero-vaccination." Serum was a medium to be used in cases of urgency, not as a curative remedy but to obviate infection and to produce a quick effect, not necessarily lasting. With vaccines and other serums not vaccines were of any use in cases of necrosis or circulatory lesions. The greatest attention should be paid to signs of susceptibility to microbes on the part of germ-bearers, for most cases of operation shock were caused by the sudden and startling development of an organism. The skillful use of vaccines and serums enabled them to anticipate this susceptibility and to counteract it.

Mr. D. P. D. Wicks of Edinburgh said that happily infection after operation was rare, but the patient was especially liable to this complication after operations on the lower part of the alimentary tract. In fatal cases the organism found was usually a streptococcus, in cases which recovered it was the colon bacillus. If an animal were given two injections of a vaccine and thereafter an intraperitoneal injection of the organism sufficient to kill a normal animal, it lived. It could stand one and a half times a lethal dose. If it had been given a vaccine on two occasions, followed the night before the intraperitoneal injection by an injection of nucleic acid, it could stand three times the lethal dose. In patients undergoing a major operation on the lower intestine he gave, ten days before the operation, an injection of vaccine of streptococci and colon bacilli; three days before the operation he gave a second dose, and on the night before 8 c.c.m. of 2 per cent. nucleic acid—this produced a leucocytosis of 12,000. He had done this on 63 cases where infection might be expected. There had been two deaths—in neither case apparently due to infection. It was a comfort to him, when a death occurred, to think of the animals upon which he had done intraperitoneal injections—those without the preliminary vaccines could and died the next morning, the others sitting up and eating their food.

Sir Arthur Wren of London said that they should ask for what purpose vaccine might be used. The

spreading increase in the cells. The Lange colloidal gold test is illustrated by four coloured plates showing the reaction in tubes, general paralysis of the insane, tuberculous and meningococcal meningitis. This edition fully maintains the value of the book as a work of reference.

Mr. Zachary Cope's little book on *The Early Diagnosis of the Acute Abdomen* has, of course, run into a second edition, and this despite its title, to which some have taken exception. Perhaps, as medical students to-day have so limited a curriculum and so much time on their hands, they would benefit by a six months' course of lectures on non-emergent but there is no "perhaps" about the benefit they will reap from six hours spent in reading these pages. A retarding after-lesson than two years consumes the first impression of sound sense, simple description and no padding. Every emergency would study such a work with zeal there would not be, in 1924, the 6,838 deaths from acute appendicitis, intestinal obstruction, and hernia recorded by the Registrar-General in 1921.

The object of Professor F. J. WYKNE's little book *Diagnosis and Functions for the enlightenment of the general reader and paper reports—for example, of rejuvenation by transplants, to prevent him from being carried away by sensational news.* Whether in this instance a little knowledge is useful may be doubted, and in spite of the author's efforts the lay public may find difficulty in following the argument. Some of the statements are open to question—such as that the pineal gland is concerned with the metabolism of sugar, that the thymus is an endocrine gland, that the fat boy in *Pickwick* is a well observed clinical study of thymus degeneration, and that nettle-rash will be found to depend on a great extent on adrenal disorder. After quoting some cases of acromegaly, observed by him in Dublin, there is the following charmingly ambiguous sentence: "Ireland has suffered from many victims of acromegaly, mostly cases in which the swelling has been limited to the head."

Dr. CHARLES FISSINGER has written for the use of the general practitioner a practical and readable book, the outcome of forty years' experience, on prognostics. An introductory chapter, in which the principal laboratory methods, including examination of serous fluids, blood, urine, cerebro-spinal fluid, and sputum are described, is followed by others on prognostics in diseases of the nervous system, the alimentary canal, liver, and pancreas, in infectious diseases, in respiratory disorders, in diseases of nutrition, especially diabetes, and in cardiovascular diseases. In dealing with each group the author considers the prognosis according to the age of the patient, the symptoms, complications, forms of the disease, and the treatment adopted. A special chapter is devoted to diseases without prognosis—that is, those in which one hand which have a natural tendency to recovery, among which he enumerates acute tonsillitis, acute bronchitis, nervous dyspepsia, membranous enterocolitis, and certain crop-like fevers, such as varicella; and on the other, those which are inevitably fatal, such as malignant diseases of lung, liver, and pancreas.

As a "first lines" to the subject *Narrating of Diseases of the Eye*, by the master of the Royal Sussex Eye Hospital, can be safely recommended; there was need for a cheap book on this subject and the work admirably meets the want; those who wish to study theory more fully can buy one of the larger and more expensive books on the subject, but this little work contains a great deal of excellent advice in a small compass and should prove valuable to those who have to spend even a few months of their career nursing in the wards of a general hospital. The opening chapters on the eye are simply written for a nurse to be possessed of. A chapter on the general nursing of eye cases is followed by one on methods of treatment and one on the theatre work; these are given on the eye and illustrations of the more important of them.

*The Early Diagnosis of the Acute Abdomen*, by Zachary Cope, M.D., M.S., F.R.C.S., Second Edition, Oxford Medical Publications, London, 1923. Pp. 100. 2s. 6d. (net).

*Narrating of Diseases of the Eye*, by Charles Fissinger, M.D., F.R.C.S., F.R.S., F.R.C.P., Professor of Public Health, St. George's Hospital, London; George Allen and Unwin, Ltd., 1923. Pp. 127. 1s. 6d. (net).

over-exposed to x rays, then x-ray burns would provide a combination of factors favourable to the development of epithelioma analogous to that which caused the development of epithelioma contagiosum in pigeons—injury, disturbed nutrition of cells, and the possible presence of a conjecturable growth-promoting factor.

Having regard to the profound degenerative changes which are produced in the gastro-intestinal tract by faulty food deficient in vitamins,<sup>1</sup> and to the ease with which, in these circumstances, harmful substances may find their way into it, or may be formed in its contents, it is possible to suppose that among these substances there may, at times, be some possessing growth-inducing properties. In this connexion attention may be drawn to the occurrence of a carcinoma of the pylorus in an early stage in one of my monkeys fed on a diet of autoclaved food, butter, and onion.<sup>2</sup> Although I cannot affirm that this carcinoma had actually developed within the period of the experiment, yet the observation is to be borne in mind in connexion with the considerations raised in this paper.

## RADIOGRAPHIC LOCALIZATION OF SPINAL LESIONS BY SICARD'S METHOD.\*

(With Special Plate.)

BY

PERCY SARGENT, C.M.G., D.S.O., F.R.C.S.,

SURGEON TO ST. THOMAS'S HOSPITAL, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

DURING a recent visit to Paris Professor Sicard kindly demonstrated to me his method of localizing certain spinal lesions by radiography after injecting an opaque fluid into the spinal theca. It provides us with a new means of diagnosis of great value.

Briefly, Professor Sicard's method is as follows. A small quantity, between 1 and 2 c.cm., of lipiodol is injected into the spinal theca through a suboccipital puncture, the patient being in a sitting posture. Lipiodol is a heavy fluid consisting of "huile d'oeillette" containing 40 per cent. of iodine, and is remarkably opaque to the x rays. The lipiodol sinks slowly downwards and is arrested at any point of occlusion of the spinal theca, so that the upper limit of a tumour, for instance, can be accurately demonstrated by x-ray examination. Similarly the lower limit of such a tumour can be shown by injecting the lipiodol through a lumbar puncture, and taking a radiogram with the patient in the head-down position. The three cases in which I have employed this method are as follows:

### CASE I (Under the care of Dr. M. A. Cassidy).

An intrathecal neurofibroma compressing the cord at the level of the ninth thoracic segment. The curved lower border of the shadow defines clearly the rounded upper surface of the tumour (Fig. 1). The two small shadows situated lateral to the main mass mark the position of a posterior root ganglion. The tumour was removed, and the patient made a rapid and uninterrupted recovery.

### CASE II (Under the care of Drs. H. G. Turney and A. E. Russell).

An extrathecal endothelioma at the level of the eighth thoracic segment. The radiogram (Fig. 2) showed the lipiodol to have been completely arrested at the level of the body of the sixth thoracic vertebra. In this case the neurological signs were such as to render it doubtful whether the case was one of spinal compression at all, whilst at the same time the exact segmental level was difficult to define. The radiographic examination immediately and almost dramatically settled both these questions. Laminectomy was performed and the tumour was removed.

\*A paper communicated to the Section of Surgery at the Annual Meeting of the British Medical Association held at Portsmouth.

### CASE III.

Fracture-dislocation at the level of the first lumbar vertebra. Here the radiogram (Fig. 3) shows the narrowing of the spinal canal and the upper limit of thecal occlusion. It also shows small droplets of lipiodol arrested at various points, probably demonstrating the presence of arachnoidal adhesions.

Even from these few cases the value of Sicard's method is obvious. Not only can it be employed to ascertain whether or not a block exists in the spinal theca, but it shows the exact position of the lesion with relation to the bones. From the operative standpoint the localization is more accurate than that which can be arrived at by neurological examination. Neurological signs may enable the segmental level to be accurately determined, but the exact position of any given spinal segment with relation to the bones is by no means easy to ascertain. Consequently a radiographic demonstration of the relation of the lesion to the vertebrae is of great value, and enables a tumour to be exposed by the removal of perhaps only three laminae arches. If, the upper limit of a tumour having been defined, a second examination is made by taking a radiogram with the patient placed head downwards after injecting lipiodol through a lumbar puncture, the lower limit of the tumour can also be demonstrated. This is a point which cannot be ascertained by neurological examination, but it is a matter of considerable importance to the surgeon, since tumours extending over many segments are sometimes encountered.

I am indebted to Sir Archibald Reid and Dr. Fildes for the excellent radiograms from the radiological department of St. Thomas's Hospital.

## Memoranda :

### MEDICAL, SURGICAL, OBSTETRICAL.

#### A LONG PAROXYSM OF AURICULAR FIBRILLATION.

Mrs. M., now aged 74, was seized on November 15th, 1919, with right hemiplegia and aphasia. The pulse was hard, regular, and slow. Early on November 17th she became faint with cold clammy skin, and later in the day it was found that auricular fibrillation had set in, the pulse rate averaging 130. On November 24th this attack ceased, and the pulse was regular at 64. On December 3rd fibrillation once more appeared, and its onset was apparently associated with the same symptoms of heart failure as before. From this time onward till July, 1921, a period of eighteen months, she was seen at first weekly and later about once a month, and during the whole of this period the pulse remained quick, and wholly irregular. At my July visit the pulse was found to be regular at 60 a minute. Since that date she has had three paroxysms of fibrillation, each of a few days' duration, and each time she has become collapsed and somnolent at the onset of the attack. When the heart is regular, the rate is slow (50 to 60), and the symptoms of heart failure at the commencement of fibrillation are doubtless dependent on the great increase of rate. As she is constantly in bed she apparently becomes injured after a time to the defective circulation. The polygraph curve during an attack shows a wholly irregular pulse without accurate spacing of the beats, such as is found in the irregular pulse of auricular flutter.

It is well known that a paroxysm of auricular fibrillation may continue for some months and then cease (Mackenzie), but it is probably very unusual for an attack to last as long as a year and a half. It seems fair to assume that during the whole of this period fibrillation was present even though the patient was seen only once a month during the latter part of the period. The onset of tachycardia is always associated with the prominent symptoms of heart failure, and these would almost certainly have been observed and reported to me by her daughter had there been any return of the normal rhythm followed by a fresh paroxysm.

E. E. LASLETT, M.D.

Hull.

might suppose that the oxidation electric wave would pass down the nerves from the area of higher potential in the glands, and since the liver had the lowest rate of oxidation—hence the lowest potential—the current would finally reach that area, whence it would return through the electrolytic system to the brain, thus completing the circuit.

The following facts were interpreted by the hypothesis that the body as a whole was an electro-chemical mechanism, the positive pole being the brain; the negative liver, the connecting wires the nerves; the salts in solution the electrolytic fluid in which the electro-chemical mechanism was immersed.

(a) When either pole—that is, the liver or the brain—was removed or destroyed, the organism perished.

(b) If the difference in potential within the cells, no less than the difference in potential between the poles (the liver and the brain), was dependent on the supply of electricity by oxidation, then, if the organism was deprived of oxygen, the existing difference in potential within the cells and within the organs was lost and equilibrium or death was established.

(c) Since the speed of chemical action and the electric conductivity were fundamentally controlled by heat and cold, it followed that in an electro-chemical mechanism there must be an optimum temperature as well as a lethal cold and a lethal warm temperature. Abdominal surgery in the colder months in unwarmed front areas has illustrated this point by a forbidding mortality rate.

(d) The opposite effects of stimulation and of exhaustion on the temperature and the electric conductivity of the brain and of the liver, the muscles and other tissues in the splanchnic area would be explained by the conception that the driving power depended upon the difference in potential between the brain and the liver, muscles and other organs. Hence, if a stimulus caused only the potential of the brain to rise and the liver remained unchanged, the difference in potential, hence the driving power, would be correspondingly less.

All these conceptions had a practical application in the treatment of shock. For the last two years treatment of patients in their clinic had been based upon the suppositions that the difference in potential between the nucleus and the cytoplasm of the cells, as well as between the essential organs of the electro-chemical system, must be maintained.

The following had been their main principles:

1. The organism needs an abundant supply of water.
2. An abundant supply of oxygen must be delivered to the cells.
3. The permeability of the selective semi-permeable membrane must be maintained within normal range.
4. Both the local and general temperature of the body must be kept at or near normal.
5. An abundance of mental and physical rest and an abundance of sleep are essential.
6. The physical structure of the cells must not be impaired by the indirect effects of the trauma of the operation nor by the anaesthesia.

Every patient should be treated individually. The practical application of the above principles was thus achieved. In "bad risk" cases nitrous oxide-oxygen analgesia (not anaesthesia) was employed together with local anaesthesia. The trauma of the operation was divided. In cases of hyperthyroidism, if the operation produced an exacerbation of the symptoms the operation was stopped at any point, the wound packed open with bawine or sterile gauze, and closure delayed. Water was urged by every route, and the wound packed open with bawine or sterile gauze, and closure delayed. Water was urged by every route, and the wound packed open with bawine or sterile gauze, and closure delayed.

Barlett's method. Oxygenation of the cells was promoted by the transfusion of whole blood before operation, during operation, and after operation, according to the indication. To assure the maintenance of an adequate circulation—which was essential to the supply of water and oxygen to the cells, digitalis was administered as a routine in those cases in which the myocardium was impaired, a condition most commonly seen in cases of hyperthyroidism. Rest and sleep were promoted by control of the environment and by narcotics, except in the presence of an already depressed liver function, as in jaundice, for the function of both the brain and the liver was depressed by narcotics, especially by morphine. In abdominal cases moist hot packs were applied immediately after operation for the support of the liver cells. The environment of the patient was controlled from his entrance to his exit from the hospital. With the gradual extension of the application of these measures based upon the electro-chemical conception the mortality rate of

every type of case had been diminished, and the operability had been extended until now no case was considered inoperable unless the stage of final dissolution was initiated. Dr. Morgagni (Paris), speaking also for Dr. Quenu and Dujar, gave in addition to the recognized type a description of a type of mitigated shock, often met with in ordinary surgery, caused, like the former, by attrition of the tissues, and which required to be dealt with by means of similar therapeutic treatment; it entitled a new chapter in surgical pathology. The prognosis of traumatic shock might be calculated by the central temperature, the analysis of the arterial tension, and by the analysis of the urine and the blood. The recovery of the urinary function, a discharge of urea and the diminution of a chemical reaction, were the best signs of a favorable prognosis. The therapeutic treatment included prophylactic measures and the removal of the shock when such had been ascertained to exist. Prompt medical and surgical treatment was a sine qua non of prophylactic care. The best surgical treatment consisted in the excision of the wound; immunization by means of an anti-shock serum had not yet given proof of its efficiency, at least from a clinical point of view. The treatment of an ascertained case of shock might be either symptomatic or causal. The former was especially useful as a means of first aid. Causal treatment was founded on the new notion of the shock. The shock was an intoxication the seat of which was the traumatic lesion; it was consequently there that their efforts were required. Therefore, what was required was the excision of the wound where the noxious albumins had their rise. Practically they were confronted with two sets of circumstances, according as the limb affected should or should not be amputated. In the latter case they should have recourse to amputation. In the former case the treatment should consist of a thorough excision of the wound, and the debrided parts should be cut off as far as possible; in any case, the seat of the malady should be thoroughly cleansed. The future progress of the wounded subject depended principally on prompt treatment. A few technical details should be emphasized: The operation should be made as quick and simple as possible. The wound should be sprinkled with a hypertonie solution, and no attempt should be made, in the beginning, to bring the edges of the wound together. The choice of the anaesthesia and the anaesthetic had not yet been settled, and required that further researches should be undertaken.

Mr. Fraser of Edinburgh divided our knowledge on the subject of shock into two periods: (a) to the end of 1915, and (b) subsequent to 1915. During the first period many theories as to its cause had been propounded. Cline and Altmeyer argued that sensory stimuli produced a rise in blood pressure from the irritation of "pressor" nerves, and that finally the vaso-motor system became exhausted. Then followed dilatation of the peripheral vessels and a fall of blood pressure. But it had been demonstrated that the vessels in shock were contracted, and that even in the profoundest shock the vaso-motor centres were not exhausted. Randall Henderson, in his acapnia theory, assumed the sequence: hypervæmia, acapnia, failure of the vaso-motor pressor mechanism, fall of blood pressure, and possibly a secondary concentration of the blood (oligæmia). Boiss regarded the fall of blood pressure as being secondary to a cardiac condition, and Altmeyer believed that the stimulus of injury resulted in an inhibition of the functions of the spinal cord. The second period of investigation coincided with the European war. Mr. Fraser's definition of shock was "a state of depression of all the vital functions of the body, the state being primarily induced by the initiation of injury on the body tissues and being characterized by a progressive fall of the blood pressure." He gave a graphic picture of the well known clinical condition. The problem was to explain the progressive fall of the blood pressure. Other symptoms were secondary to this. In health there were three factors maintaining the blood pressure—the heart, the vaso-motor mechanism, and the blood stream. There was no interference with the nervous mechanism of the heart even in profound shock, and Mann had shown that apart from myocardial disease an efficient contraction of cardiac muscle could be guaranteed so long

the patient had much glycosuria; but if very bad 50 grams of sugar should be given and 60 units of insulin; but as much as 140 units might be required in the twenty-four hours. If the patient had glycosuria, blood sugar estimation was not essential; but if sugar-free, an occasional estimation was necessary for the control of the dose. It was possible to preserve blood for sugar estimation by adding one drop of formalin to 5 c.c. oxalated blood.

Dr. J. A. Nixon (Bristol) said that this was a very memorable discussion; he spoke of insulin perhaps prematurely, but certainly enthusiastically. He would like to know if a patient was any better for being sugar-free when he had a high blood sugar; mere glycosuria was not a sufficient guide in treating patients. Was such a patient safe when gaining in weight and in sense of well-being? Provided the sugar threshold was known, if glycosuria occurred with a normal blood sugar it might be said that glycosuria was the safest point. But were patients with hyperglycaemia safe to send out of hospital for treatment? Dr. Nixon recounted the case of a patient who had had 20 units of insulin daily for three days, and then developed temporary aphasia in which repetition of syllables occurred; he was given glucose, and talked moderately well in two days. He had had angina pectoris before this. Was this a symptom of hypoglycaemia? Another patient complained of tingling in the lower limbs and swelling in the feet. Was this due to hypoglycaemia? He considered Woodyat's formula of the greatest value in adjusting the minimal adequate diet. Should insulin be given to a true diabetic with a high sugar tolerance? Dr. John Rennie (Glasgow) referred to the treatment of ten cases, in all of which an attempt was made to get them sugar-free by dieting before commencing treatment with insulin. As a rule the chronic cases with a low tolerance did well. With sugar and acetone present in the urine blood sugar estimations were not necessary, and in cases showing much acidosis the urinary sugar might be neglected. On a constant carbohydrate intake the insulin might perhaps be reduced and the tolerance partly restored. He had been unable to find any experimental evidence that insulin was absorbed through the skin. Dr. E. P. Poulton (London) had tried to determine if there was any increase of sugar tolerance in mild cases—that is, those which became sugar-free on diet restrictions after prolonged treatment with insulin; the rise of blood sugar was estimated after giving a dose of 25 grams of sugar, and the experiment repeated after a period of treatment. The diet yielded about 40 calories per kilo, and the patients were walking about. After 60 units a day for thirty days there was no evidence of improved tolerance in one case, though the patient gained in weight. In a second case there was some distinct improvement; in a third, perhaps a slight improvement; in a fourth case, after eighteen days' treatment, there was a slight but definite improvement.

Dr. O. Leyton (London) divided cases into two groups—those of recent onset, and those of longer duration in which the pancreas had been saved as far as possible by dieting. In the majority of cases if the patient was given a general anaesthetic—whether chloroform, ether, or nitrous oxide—the sugar tolerance fell. Insulin should be given to make the blood sugar below rather than above normal. In recent cases an attempt should be made to keep it below 0.09 or 0.07 per cent. He detailed certain symptoms of hypoglycaemia. In one instance a boy of 5, who was suffering from Hirschsprung's disease as well as diabetes, suddenly became comatose, and a man over 40 had an epileptiform seizure preceded by dizziness, sweating, tremors, and slurred speech. Dr. A. P. Thomson (Birmingham) discussed the treatment of thirty cases, two of which had definitely recovered tolerance. It was impossible to treat a fool with insulin. If the patient would not stand dieting insulin was of no use. Blood sugar estimations were essential when giving large doses of insulin, as in cases of coma, but at other times treatment could well be carried on without. He related the case of a young man aged 21, who, though nearly in coma, did well upon insulin, but suddenly developed bilateral cataract while sugar-free; he mentioned also two cases of haematuria following large doses. Toxic symptoms might occur

without hypoglycaemia and be relieved by 0.5 c.c. pituitrin. Dr. F. A. Roper (Exeter) considered it important that a patient should be under strict observation before insulin treatment was begun. He described a severe case of diabetes in a man aged 56 in whom the onset coincided with an attack of dysentery, and who now had albuminuria also and a strongly positive Rothera reaction; his general condition contraindicated prolonged alimentary rest; a comparatively small dose of insulin (10 units thrice a day) rendered him unconscious, but he made a complete recovery after a dose of glucose intravenously. Dr. Waters (I.M.S.) asked if the potency of insulin was affected in any way by the temperature at which it was stored; and Dr. Clarke Begg (Swansea) asked what instructions should be given to patients on leaving hospital. Should the aim be to get them sugar-free, or should they have a small degree of glycosuria?

Dr. Banting, who replied at the request of the President, said that the cause of the deficiency of the islets was not known. Continued treatment was necessary in severe cases, and the patients could be trained to give injections to themselves. Larger doses were always necessary at the outset of treatment; when two doses a day were given the larger should be in the morning; the ideal was to balance the amount administered to correct the deficiency. It was easier to treat a long-standing elderly diabetic than a young and early case. An attempt should be made to maintain the blood sugar at its normal level; raised blood sugar stimulated the pancreas. On the patient's discharge from hospital a detailed letter was sent to his family physician; but by this time the patient was thoroughly acquainted with the routine. Of the symptoms of hypoglycaemia the most frequent were a feeling of uneasiness, of impending disaster, trembling; in children pallor, increased pulse frequency, and sweating. These symptoms were succeeded by incoherent speech, hunger, sleepiness, and coma. The rate of fall of blood sugar was influential in determining the onset of symptoms, which might not occur till 0.05 per cent. was reached, and as low a figure as 0.032 per cent. had been recorded. Adrenaline (mx to xv) would usually render a comatose patient conscious, owing to its rapid action in turning out glycogen from the liver; when conscious the patient should be given 10 to 20 grams of glucose by the mouth. Insulin, if kept at room temperature, did not lose its potency in six months, but Dr. Banting had no knowledge of the effect of high temperatures. There was no reason why a diabetic should not be treated as well by the general practitioner as by the specialist.

## SECTION OF SURGERY.

Wednesday, July 25th.

THE discussion on the treatment of obstruction of the colon at the first session of the Section of Surgery attracted a good audience. The President of the Section, Sir Henry Gray, in introducing Mr. Arthur Burgess of Manchester, said that he was grateful for the compliment paid himself in being elected President of the Section, as it was probable that this would be the last occasion on which he as a Britisher would be able to attend. Mr. Burgess indicated that his intention was to deal with obstruction of the colon by gross mechanical obstacles. He discussed the chances of obstruction of the colon in relation to cause, and pointed out that malignant disease was responsible for acute obstruction in the proportion of 9 to 1; in regard to the location on one side of the body or the other, the proportion of cases on the left compared with the right was as 6.5 to 1. He approached the discussion of the appropriate treatment of acute obstruction of the colon mainly from the clinical standpoint, and considered the cases as they presented themselves prior to the operation under three groups. In the first came those in which it could not be ascertained whether the obstructions were in the ileum or in the colon; the second group included cases where the obstruction was of the colon, but its precise situation therein was not known; the third group included cases where the site of obstruction in the colon could be definitely ascertained. With increasing experience the number in

## THE PORTSMOUTH MEETING.

The ninety-fifth Annual Meeting of the British Medical Association, held last week at the great seaport town of Portsmouth, has played a notable part in forwarding the three chief aims for which the Association exists—namely, to promote the medical sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members.

From each of these points of view—the clinical and scientific, the medico-political, and the social—the Portsmouth meeting was highly successful. It will be remembered by all who took part in it for the practical tone of the discussions in which the Representative Body business-like spirit in which the Representative Body carried through its long programme; and, perhaps most of all, for the abounding hospitality extended by the Portsmouth Division of the Association, by the Mayor and Corporation, by the Naval authorities, and by residents in the town and neighbourhood, both medical and lay. This gathering of more than a thousand medical men and women from all parts of the British Empire demonstrated something of the power wielded by the British Medical Association in consolidating members of the profession for their own good and in the public interest. Everyone who heard the President's address and followed the work of the meeting must have been impressed both with the universality of Medicine, and with the closeness of its contact with educated lay opinion in all that affects the welfare of the community. The growing public interest in medical matters was reflected in the zeal with which the proceedings of the Representative Body and the Sections were followed by the lay newspapers, and gave point to Mr. Child's dictum from the Presidential chair that "the advent of a wide-awake and informed public tends to keep the profession up to the mark."

The scientific and clinical work of the meeting lost nothing in interest or value from a reduction in the number of Sections; they were 16 this year as against 19 at Glasgow. In another column we begin the publication of summaries indicating the scope of their work, in anticipation of the full reports to be published in subsequent issues. The attendance at most of the Sections was good, and interest was well maintained throughout. The discussion on diabetes, in the Section of Medicine, attracted a very large audience to pay honour to Dr. Banting of Toronto, and hear from his own lips some account of his discovery of insulin, and learn the latest news of its application to clinical practice. Another big gathering was that in the Section of Obstetrics and Gynaecology on July 26th, when Mr. Comyns Berkeley opened a spirited debate on the use and abuse of forceps. To illustrate further the unacademic nature of the sectional work this year, and its interest for the general practitioner, we may mention the discussions on the etiology and treatment of heart disease in early life, and on chronic bronchitis, in the Section of Medicine; Dr. Cameron's attractive introduction to a discussion on the nervous child; the surgical symposium on how to treat acute primary affections of the hand; and the debate by the

pediatricians on summer diarrhoea. The pathological proceedings showed no aloofness from clinical medicine, and the public health officers—like the radiologists, the orthopaedic surgeons, and the experts in venereal disease—considered in their several Sections topics of interest to others than specialists. The anaesthetic discussions, both in the special Section and in the Section of Surgery, were eminently practical, and the same can be said for the excellent debate on ophthalmology in its relation to the Army Navy, and Air Force, which brought together civilian ophthalmic surgeons and many medical officers from the three services.

In the premier naval port special attention was naturally given to the Section of Naval and Military Hygiene, in which papers were read by prominent officers, and several demonstrations were given of officers, particularly to those in the services. The Sections were not organized on any fixed pattern. Thus, while the oto-rhino-laryngologists had a very varied programme, the Section of Tuberculosis focused attention on three problems, and the medical sociologists concentrated upon three aspects of a single topic. Lastly, in connection with the scientific work done at Portsmouth, a word of praise is due to the organizers of the Pathological Museum.

The four days preceding the sectional meetings were devoted, as usual, to the transaction of medical and political business by the Representative Body and to a discussion of the domestic affairs of the Association. A feature of these meetings in recent times has been the growing number of delegates from Overseas Branches, and it is pleasant to be able to record that this year their number was greater than ever before. A full report of the first three days' work of the Representative Body appeared in last week's *STANDARD*, and the concluding day is reported in the same detail this week. From these accounts and from the outline sketches published last week in the *STANDARD* at page 151, and this week at page 198, it will be seen that the programme, though long and intricate, was completed with great expedition under the able chairmanship of Dr. Wallace Henry. Of the controversial matters discussed at full length, mention must be made here of the scheme for closer co-operation between the British Medical Association and the Society of Medical Officers of Health, which was adopted by a large majority after every objection had been heard; and the hospitals debate, which ended in putting off for another year a solution of the "staff funds" problem. On the first subject a working agreement has been reached; on the second, professional opinion is still sharply divided. The outstanding domestic event brought before the Representative Body was the recent acquisition of a new headquarters building for the Association in order to give pace with its growth in membership and activity. The action taken in this matter by the responsible officers was heartily endorsed by a unanimous vote. For information on this and many other topics of professional interest members must turn to the very full reports in the *STANDARD* and the running commentaries in the *JOURNAL*.

As we have indicated already, this year's Annual Meeting was notable for the success of its social side. The hospitality of Portsmouth and Southsea, and their neighbours, was lavish. The President and the indefatigable Local Honorary Secretary, Mr. Scott Ridout, and their many willing colleagues devoted themselves heart and soul to make the meeting not only pleasant, but profitable.

THE PORTSMOUTH MEETING.

would give a patient the chance of further childbirth, while if the tube were already too much damaged salpingostomy would prevent permanent ill health. A lively discussion ensued in which the following took part: the President, Dr. Carlton Oldfield (Leeds), Dr. John Campbell (Belfast), Professor R. W. Johnstone (Belfast), Mr. Leonard Phillips (London), Dr. Gilmore Currier (U.S.A.), Mr. Rivett (London), and Mr. Hendry (Glasgow). A communication from Mr. Blair Bell (Liverpool) was read by the President. Mr. Bourne closed the Section's proceedings by a brief reply.

#### SECTION OF PATHOLOGY.

It is proposed to publish next week the full report of the first day's proceedings in the Section of Pathology and Bacteriology, when a discussion took place on diseases of the stomach, particularly with reference to modern methods of investigation, opened by Dr. Charles Bolton, F.R.S.

Thursday, July 26th.

Professor H. R. Dean, in his paper on serum reactions, pointed out that the reactions which take place *in vitro* between antigen and antibody are in a sense by-products of other research, the primary object of which was the means by which bacterial disease may be prevented or cured. The discoveries of agglutination, precipitation, and complement deviation were made by men interested in the broad and general principles of immunity, and the valuable practical methods were the outcome but not the primary objects of their discoveries. The remarkable specificity of these reactions was observed during the progress of the earliest work on the serum reactions, but the nature of this specific reaction remained to-day as great a mystery as ever. Professor Dean recalled several examples illustrating the specificity of serum reactions, and mentioned Nuttall's work on the differentiation of the blood serum of nearly allied species of animals by the precipitation reaction, the agglutination reactions of the typhoid-paratyphoid group of bacteria, and the separation of pneumococci and meningococci into groups. As Andrewes's work had shown, serum reactions could be made to demonstrate variations occurring in the individuals comprising the population of a pure bacterial culture. He gave instances in which the serum of a wounded soldier suffering from mild anaphylaxis reacted with dilutions of the tetanus antitoxin which had been used to inoculate him, but not with normal horse serum. Other examples of extreme specificity mentioned by Professor Dean were the production of specific antibody by the injection of the proteins or antigens of the lens of the eye, and the antigenic differences between the protein fractions of one and the same sample of serum as shown in Dale's experiments by the use of the guinea-pig uterus. In the second part of his paper Professor Dean considered the significance of a positive serum reaction. In typhoid and allied infections the significance of a positive reaction was purely diagnostic. In the case of the Wassermann reaction there was, in addition to the diagnostic, a therapeutic and prognostic interest. The complement fixation tests for gonorrhoea and tuberculosis were by no means so firmly established. In the days when the opsonic index was a popular method of diagnosing tuberculosis it was claimed that the majority of tuberculous patients could be shown by the opsonic index method to be deficient in antibodies. At the present time the complement fixation reaction was more popular or was regarded as affording better prospects of success. Even if the specific opsonin was quite a different kind of antibody to the complement fixing antibody it would be remarkable if tuberculosis could be recognized by deficiency of the one and superabundance of the other. Judged by the one reaction tuberculosis was to be suspected if the antibody content of the serum was below normal; judged by the other if the antibody content was above normal. Thus our interpretation of the significance of a positive reaction was somewhat empirical and founded largely on the practical experience of different workers, using different reactions for the diagnosis of different diseases. Professor Dean considered that the facts could be covered by the hypothesis that the formation of specific

antibody was induced by the introduction of the antigen into the animal body, was continued as long as the antigen persisted in the tissues, and came to an end when all traces of the antigen were destroyed. A positive serum reaction would thus be evidence of the existence at that time of antigen in the tissues. Evidence in support of this hypothesis was cited from experiments designed to test both the presence of antigen and antibody in the tissues. The sharply localized reactions which sometimes appeared when soldiers received repeated injections of antitetanus serum might be explained by the existence at these spots of a surviving and limited focus of antibody formation, and such a small focus of antibody formation situated at the spot where a trace of the originally injected antigen still persisted might have acted as a sufficient stimulus for the production of a small quantity of antibody. In conclusion Professor Dean pointed out that whereas during the last twenty years there had been progress in technique and much ingenuity had been directed towards the improvement of existing methods, very little effort had been made towards the solution of the underlying problems involved in serological reactions.

#### SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Wednesday, July 25th.

The proceedings of the Section opened with a discussion on the nervous child. The President of the Section, Dr. H. Davine (Portsmouth), took the chair, and in a brief introductory speech sketched the scope of the Section's work, emphasizing the change of outlook of psychiatry, which was now coming to be regarded more as a branch of general medicine. A very interesting and lively discussion ensued, which was closely followed by a large and attractive audience.

Dr. Hector Cameron (London) opened with a paper which was full of interest, wit, and great psychological insight. He began by drawing attention to certain physical peculiarities which characterized the nervous child. These he classified as amyotonia, resulting in a characteristic stance, with lordosis and a protuberant abdomen, as pallor from a vasomotor anaemia, as postural or lordotic albuminuria. Further characteristic physical symptoms were attacks of abdominal pain which might be mistaken for chronic appendicitis, enteroptosis, and constipation. Such children, again, possessed but a low immunity to infections, especially of the catarrhal kind. Frequently also irregularities of the temperature were found. The origin of many of the nervous symptoms was to be found in a study of the parents. The young child was highly suggestible, and very quick to catch and make the most of any anxiety which is aroused in the household by its refusal to take food, etc. Timidity on the one hand and excessive foolishness on the other could be traced to faulty management on the part of the parents. Nervous children often displayed a strongly negativistic attitude, which could be well seen in certain cases of anorexia nervosa. The desire to attract attention or self-assertion was another common symptom in the nervous child, which might sometimes explain acts and behaviour which were either distressing or even indecent. Dr. Cameron illustrated his paper by several interesting slides, showing the characteristic stances and postures of the type of child under discussion.

Dr. McFie Campbell (Boston) agreed that physical infirmities might be reflected in behaviour defects. The psychologist, however, would be most interested in those cases where no physical defects could be found, and such cases could include loss of sleep, anorexia nervosa, morbid fears, and a whole variety of failures of adaptation to environment. Parents should realize more that children were not merely an appanage of the household, but were individuals. The suggestions of the mother not seldom caused great difficulties, and in the treatment of these cases the whole home life of the family must be carefully studied. Children should be more left to develop their own individuality. Dr. Helen Boylo (Brighton) welcomed Dr. Cameron's paper, especially as it combined the study of both the physical and mental aspects of these cases. She

We may conclude this brief survey of the information about insulin contained in this issue of the *Journal* by echoing two of Professor Macleod's observations. The one is that without experiments on animals we should not now be in possession of the knowledge of the mode of action of insulin which justifies its commendable use in the treatment of severe cases of diabetes in man, and in particular of its great value in diabetic coma. Until the laboratory investigations had furnished perfectly definite results serious attempts to carry the investigations into the clinic could not be made. The second is the credit he justly gives to those responsible for producing insulin on a large scale for clinical use, that they would have succeeded in so short a time in their work.

#### TEACHING OF OPHTHALMOLOGY.

#### THE HEALTH OF LONDON.

The London County Council, like other public authorities in these days of retrenchment, cuts down rigorously its output of paper and printing, including annual and other reports. Its Public Health Report for 1932\* contains in 150 octavo pages the report of the County Medical Officer and School Medical Officer, and the report on main drainage and housing. In an introductory note Sir William Hamer refers to some of the salient facts in the health history of the year. There was a heavy prevalence of infectious diseases—influenza, measles, whooping-cough, scarlet fever, and diphtheria—in the early months, but summer diarrhoea was checked by the wet cool summer and the activities of child welfare centres and other agencies, so that the rate of mortality from that cause under one year of age was unprecedentedly low—6.26 per 1,000 births, as against 18.63 in the previous year, and 24.28 in the four years 1911-14. As a result of this the all-age death rate was 15.5, or only 1 per 1,000 above the record minimum of the previous year. Of typhoid fever there were only 264 notifications—the very minimum for London—and 1922 has been the eleventh year in succession with almost complete absence of an autumnal rise in the curve of prevalence. This leads Sir William Hamer to review the whole question of typhoid incidence. As in cholera in the past, cases of typhoid tend to occur in groups, sometimes in circumscribed areas or in institutions, and, as pointed out in a previous report (1911), such groups commonly occur in streets occupied by families living in poverty, but not in extreme poverty. Two theories have been advanced in explanation—one that of healthy carriers, the other, not infection from person to person, but the continued operation of a common cause. The latter is the hypothesis adopted in the report, and the common cause is food supply, the food responsible being immature flat-fish. That thesis is defended in most interesting fashion in the body of the report, but in the present brief paragraph we are dealing only with the introductory note. Turning to plithis, it is observed that there has been some increase in the registered death rate at young adult ages, but this is attributed to the debiting (Sir William says crediting) to London of deaths which formerly have been registered in health resorts or abroad. The United States policy of limiting immigration has had in respect of health an indirect favourable influence in this country, though which many emigrants, some developed acute infectious disease, used to pass on their way to America. In 1922 administrative progress has been made in tuberculosis and venereal disease treatment schemes. A February census of homeless persons showed a great reduction as compared with pre-war years, and the same remark applies to occupants of common lodging houses and furnished rooms. Similarly the census of 1921 showed some diminution in overcrowding. We hope in a later notice to deal more fully with some parts of the report.

an examination in ophthalmology as part of the final show that there is no particular difficulty in conducting posal. The experience of the Irish examining bodies has wards and out-patient department in the time at his disposal. The experience of the Irish examining bodies has required course of lectures and practical instruction in the great difficulty in the student finding time to attend with general medicine and surgery, and there should be no subjects. Ophthalmology, however, is intimately bound up to a certain extent with this and with other special be expected to give much attention to it; they will gamble they will not be examined in a special subject they cannot was the case even twenty years ago; if students know that student of to-day has to undertake far more classes than very true that the curriculum is overloaded, and that the recommendations to the licensing bodies. It is of course logists that it was too soon to judge of the effect of the ophthalmoscope, and the Council of British Ophthalmion in diseases of the eye, refraction, and the use of the curriculum was that each student should receive instruction the licensing bodies for the improvement of the medical of the recommendations made by the Council last year to Council decided to inform the Ministry of Health that one also mentioned the letter from the ophthalmologists. The tion to the report of the Departmental Committee, and the Chairman of the Examination Committee drew attention at the meeting of the General Medical Council on June 1st evidence of satisfactory work in his department shall be directly to the ophthalmic surgeon to determine what the The ophthalmologists object to this that it leaves it enconnection therewith has reached a satisfactory standard that his schedule should not be signed unless his work in ophthalmology of not less than ten weeks' duration, and should attend a course of practical instruction in took limited action in 1919 by requiring that every student It will be remembered that the General Medical Council a degree or a diploma to be examined in ophthalmology, rule the examining body does not require a candidate for which students receive, and pointed out that as a general fault with the limited amount of training in the subject ophthalmology." The Departmental Committee found trying examination in medicine should be examined in insist that every student presenting himself for a qualification examination in the General Medical Council "to Blindness, inviting the General Medical Council "to position has been fortified by the recommendation of the examination conducted by ophthalmic surgeons. Its a sound knowledge of practical ophthalmology in an passed the qualifying examination unless he has shown and urges that no student should be considered to have Ophthalmologists takes up once more its parable of 1919 printed last week (p. 147) the Council of British for the correspondence with the General Medical Council

type and of a clinical character.

tion. Any examination, however, should be simple in type and of a clinical character. examiners at the present time have the necessary knowledge of diseases of the eye to conduct such an examination. The second is the credit he justly gives to those responsible for producing insulin on a large scale for clinical use, that they would have succeeded in so short a time in their work.

welfare work with better midwifery service. Two gave better education as the cause, four reduced birth rates, five improved sanitation and social conditions, and two the use of dried milk. He personally had come to the conclusion that the principal factor was improved education, both general and special, and that there was good reason to believe this improvement would be permanent. In the discussion that followed Dr. Peeke (Derbyshire) thought that Dr. Wheatley had underrated the effect of improved sanitary conditions, especially the conversion of privy middens. He also regarded the introduction of summer-time as a factor of importance. Dr. Brackenbury (Hornsey) agreed with Dr. Wheatley as to the supreme importance of education, including direct instruction in personal and domestic hygiene. He thought the effect of the work of the child welfare centres had been exaggerated. Dr. Kirkhope (Tottenham) emphasized the importance of the education given to mothers at the pre-natal and infant clinics. Dr. Clark Trotter (Islington) contended that the most important part of child welfare work was in visiting the homes and thus improving the environment of the child. Dr. Miller (Radnorshire) had found a lower percentage of breast-feeding in rural than in urban districts. He agreed that home visiting by health visitors was the most important factor in hygienic education. Dr. A. Bullough (County Medical Officer, Essex) observed that heredity had an unfavourable influence on infant mortality, since the careless mother often had the largest family. The mother formed the true environment of the child, and everything depended on her knowledge and character. Education fitted her to receive the instructions of health visitors and others. Professor Wynne (M.O.H. Sheffield) expressed some scepticism as to the value in these respects of the instruction given in elementary schools. Dr. Wheatley replied on the various points raised in the discussion, and maintained the supreme importance of education and the real value of the existing system.

Dr. H. Scurfield read a paper on the value of watercress in dietetics, especially to urban communities. Watercress, he said, was a form of green food eaten uncooked and available at low cost all the year round. Its value as an anti-scorbutic was well known, and there was reason to believe that it was also rich in the other vitamins, as well as containing iron, iodine, and calcium. In some of the large glass farms he had visited every care was taken in its growth and handling, and the danger of infection with typhoid fever or other water-borne disease was eliminated. Inspection of such watercress beds was a simple matter. Dr. Smedley said that watercress had fallen out of favour in this country, though it was largely consumed in France with excellent results. Dr. Wheatley hoped that careful experiments into the dietetic value of watercress would be made, as general impressions were not sufficient to act on in view of the possible risk of infection as disclosed by the late Sir Shirley Murphy. Dr. Scurfield, in reply, pointed out that he advocated only the increase of watercress produced on a large scale and under sanitary conditions.

#### SECTION OF DISEASES OF CHILDREN.

Thursday, July 26th.

In opening the first discussion, on acidosis and alkalosis in children, Dr. Cammidge said that it was important to understand clearly what was meant by those terms. Acetonuria had been and often was used synonymously with acidosis, but the two conditions were by no means identical and either might occur without the other. The term ketonuria should denote the presence of acid products of abnormal metabolism in the urine, and acidosis should be reserved for the true condition. During metabolism be reserved for the true condition. During metabolism there was a tendency for acid bodies to appear in the blood, but the reaction of blood and tissue was kept constant by the action of buffer substances. The entrance of acid products into the circulation decomposed some of the bicarbonates and produced a relative excess of carbon dioxide. The respiratory centre was thereby stimulated and the carbonic acid was eliminated by means of the lungs. Nor-

plished, but in pathological conditions they might be depleted and the percentage of bicarbonate in the blood permanently diminished. There would be a corresponding reduction in the capacity of the blood to transport carbon dioxide, which would accumulate in the tissues and give rise to symptoms of suffocation and finally death. Acidosis, then, was a condition in which the concentration of bicarbonate in the blood was reduced below the normal level. Acidosis in children occurred chiefly in diabetes and in cases with recurrent "bilious attacks." Nothing had been published on alkalosis in children as far as he knew.

Dr. Ruth Verney (Edinburgh) gave the results of her investigations on buffer substances in the blood in children. Protein acted in this way, as well as weak acids and bases. One of the most powerful buffers was haemoglobin. The President, Dr. Edmund Cantley, mentioned his own uncertainty in regard to the differentiation of acidosis and alkalosis and their effects. He asked at what stage ketosis became acidaemia. Dr. E. P. Poulton said that although he himself had suggested some three years ago the nomenclature adopted by Dr. Cammidge, he now preferred the terms alkalaemia and acidaemia as connoting a diminished or an increased hydrogen ion concentration. He referred to the clinical and experimental aspects of the association of alkalaemia with tetany. Dr. Eric Pritchard considered that health in children depended more on the extent of the alkaline reserve than on any other condition. The kidneys were not the only means of getting rid of metabolic products; the faeces were probably a more important source of elimination of bases. In premature infants the absence of a calcium reserve constituted a serious danger. Dr. Catherine Chisholm said that in her experience acidosis occurred frequently in pneumonia, and that the disease responded quickly to large doses of alkalis. Dr. Cammidge replied to the discussion.

Colonel R. J. Blackham read a paper on cow's milk in infant feeding. He discussed the form in which cow's milk should be used when breast-feeding was impossible. Raw milk was dangerous because of the bacterial infection it could engender. Besides sterilizing the milk, heat had the advantage of diminishing the toxic properties of foreign casein. In the speaker's experience condensed milk was apt to make a child fat, flabby, and dull. Milk powder had the advantage of uniformity, while it was less liable to contamination and retained most of its vitamin content.

#### SECTION OF LARYNGOLOGY AND OTOTOLOGY.

Thursday, July 26th.

In opening the discussion on internal ear deafness, Dr. Dan McKenzie (London) began by deploring the disparity between our anatomical as opposed to our pathological knowledge of the labyrinth. He described the well known difficulty of assessing the value of tuning-fork tests in deciding whether a case was of middle or inner ear deafness. With regard to obstructive deafness, nobody had thrown a doubt upon the correctness of the inferences to be drawn; but he described a case in which all the classical signs of nerve deafness were present in which removal of impacted cerumen was followed by immediate relief from all deafness. Mixed deafness was the commonest type of all, and the affection of the labyrinth in these cases might be merely a functional derangement. The commonest cause of nerve deafness was middle-ear disease, and the prognosis of nerve deafness in middle-ear disease was grave unless the latter could be arrested. Myxoedematous deafness was of this type, but yielded readily to thyroid medication. He next dwelt upon the relation between the vestibular reflexes and nerve deafness; they coexisted in acute but rather in chronic labyrinthitis. Vertigo might attend upon almost any ear disease, but tinnitus was usually tympanic. Having dealt with noise deafness, senile deafness, syphilitic and toxic, he concluded by sounding a note of hope even in the present state of ignorance. Thirteen speakers took part in the discussion. Mr. Mollison (London) grouped deafness into qualitative and quantitative. In the qualitative types there was a loss either of the upper or lower tones, whereas the remainder of the scale was unaffected. In

November, after inquiring into "the conditions of service in all branches of the Medical Department." The report now issued will materially affect the development of the medical services, and is of considerable interest. As regards medical officers, whilst some inequalities and anomalies are recognized in connection with allowances and fees, no change is suggested, and the existing salary scales of £500 to £600 for second and £600 to £700 for first grade officers are considered satisfactory. Certain changes are recommended in the distribution of districts, and also (on the plea of economy) the abolition of the Demerara River medical officership. The importance of a qualification in tropical medicine is emphasized, and it is suggested that a recognized degree or diploma in this subject should in the future be required from candidates for appointment, whilst any member of the service not holding such a qualification should acquire it during his next period of leave, or as a preliminary to promotion to Grade I. Payment of class fees and an extension of two months' leave on full pay are recommended in the case of applicants for study leave approved by the Surgeon-General. This concession means, of course, that the officer concerned must devote to the course selected the four months' leave to which he must be entitled at the time of application, in addition to the two months' extension. It is also subject to an undertaking to refund all amounts received under this head in case of failure to return to the colony on completion of the course, or to remain in the service for at least two years from that time. Considerable extensions of the public hospital at Georgetown are recommended, and a scheme is put forward for the appointment to the hospital staff of specialists in eyes, nose, throat and ear, venereal diseases, and tuberculosis; the first of these appointments—that to the eye department—to be made at once, on a scale of £700 rising by yearly increments of £50 to £900 per annum, with free quarters or house allowance; the others as finances permit. The report also provides for the appointment of a non-medical radiographer, to relieve the bacteriologist of the duties he at present discharges in the x-ray department. It is suggested that the fees earned by this increased staff should materially relieve the revenue. In the Public Health Department it is recommended that medical officers of health acting as port medical officers should be permitted to charge and retain overtime fees for work done between 6 p.m. and 8 a.m. Finally, it is laid down that all future appointments to the medical service should cover the duties at the league centres. The report also covers the nurses' and dispensers' departments.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

The summer general meeting of the above association was held on July 25th, at "The Corner House," Portsmouth. The chair was filled, in the absence of the president (Sir William Taylor, K.B.E., C.B.), by Dr. J. A. Macdonald, vice-president, who congratulated the members present on the exceptionally large attendance, one of those who were with them that day having come all the way from far-off Donegal. The luncheon which took place the same day was greeted by the presence of several ladies, and the chairman said he was glad to know that an increasing number of women doctors who had studied in Ireland were joining their ranks. They were thus supporting an association which was the first medical society in England to admit women to membership. In fact, one of the original members was a lady who was still practising in the West of Ireland. A committee appointed by his Excellency the Governor, to consider and report on the medical services of the Colony, to the Court, No. 28/1922. The Atorney Co., Ltd., printers to the Government of British Guiana.

NOTIFICATION OF TUBERCULOSIS.

The Ministry of Health has issued to all medical practitioners in England and Wales a circular letter, dated August 2nd, expressing its concern that more than 40 per cent. of the persons dying from tuberculosis have not previously been notified as suffering from that disease. Under the Public Health (Tuberculosis) Regulations, 1912, it is the duty of every practitioner, within forty-eight hours of his becoming aware that any patient of his is suffering from tuberculosis, to notify the case to the medical officer of health of the district, unless he has reasonable grounds for believing that the case has already been notified to that officer. Attention is called to the fact that the regulations expressly require that every notification and every document relating to a person so notified is to be regarded as confidential by the medical officer of health and every other person who has access to the documents. Further, if the practitioner considers that the circumstances of any particular case are such as to render it unnecessary or contrary to the interests of the patient for his home to be visited by the medical officer of health or his staff, it is open to him to arrange to dispense with such visits. It is of course

A PORTRAIT OF SIR CHARLES SCARBURGH.

Thanked the generosity of Dr. M. W. James Smith of Sheffield a fine portrait in oils of Sir Charles Scarburgh has just come into the possession of the Royal College of Physicians of London. It was known that two portraits of Scarburgh were in existence—one in the Hall of the Barber Surgeons and the other in the collection at Temple Newsam, Whitehall, Yorks. Lately the collection at Temple Newsam has been dispersed, and Dr. James Smith found that the portrait of Sir Charles Scarburgh was for sale. He lost no time in finding the seller, and purchased the portrait; he has now generously presented it to the College of Physicians, where it will be on view shortly. Although this portrait was styled in the sale catalogue the portrait of a "Navigator," on account of mathematical instruments being on the table, Dr. James Smith had no difficulty in establishing its identity by comparing it with an engraved portrait of Scarburgh by Van der Gucht. Scarburgh was a distinguished physician in the seventeenth century, and occupied the position of physician to Charles II, James II, and William III. He was deeply interested in mathematics, and was the friend of Harvey, who begged to him his velvet gown and his little surgical instruments of silver."

"God Save the King," in the heartiest manner possible, entire company singing, was brought to a close by the hospitals enjoyed of periodically renewing old friendships. Dr. James (Thompson) for giving to these men and women the same opportunities that the ex-students of London They had much reason to thank an army surgeon (the late students together in Dublin, Belfast, Cork, or Galway. service, old comrades they had not seen since they were they derived from meeting, after years of perhaps foreign the spirit of camaraderie were rewarded by the pleasure Dr. James Stewart, said that their members who cultivated world over. Dr. Douglas, whose health was proposed by fellowship for which their profession was noted all the medica had imbued them with those high ideals of good of a quarter all that time. It was evident that the means thirce yearly, and that there had never been the whither chairman had told them, forty-five years constantly meeting shade of political and religious opinion had been, as the to learn that an association of Irishmen representing every was proposed by Mr. Hempsom, who said it was refreshing were commendably short. The health of Dr. Macdonald England. The speeches which followed the chairman's

nervousness and there was the difference in mental state between examiner and examinee to be considered; prowess in games he considered as very important as showing psychomotor responses. Lieut. Colonel N. J. Crawford Rutherford asked whether a standard could be arrived at to eliminate the number of recruits discharged within six months as unfit due to middle-ear disease. In spite of auscultatory examination of all recruits on enlistment, discharges for middle-ear disease continued to head the list. He also considered it advisable to put recruits through mental tests on enlistment in order to have some record of their mentality, and to prevent subsequent discharges as "mentally inefficient" when the recruit's mental attitude towards soldiering had altered. Lieut. Colonel Salisbury Sharpe agreed that marked deviations from the average of stature either above or below were disadvantageous to the individual. He thought that the only satisfactory method of doing hearing tests was with a stop watch which could be started or stopped without any audible noise. The opener replied that a War Office committee had been appointed to deal with the question of middle-ear diseases. Aural surgeons were by no means unanimous in their opinions as to whether a recruit should be passed or not, and he cited a case where three specialists had differed. Time did not permit of Surgeon Commander K. Digby Bell's paper being read in the forenoon, but it was dealt with at a special demonstration at the Royal Naval School of Physical and Recreational Training that afternoon. Wing Commander H. E. Whittingham read a paper on the life-history and bionomics of *Phlebotomus papatasi*, illustrated by lantern slides. Major H. Homo asked whether it was correct that phlebotomus fever could be diagnosed by the leucocyte count as claimed by certain German workers. Wing Commander Whittingham replied that it was possible as the result of a blood examination by an accustomed pathologist to give a fairly certain diagnosis.

#### SECTION OF TUBERCULOSIS.

Wednesday, July 25th.

AFTER a few preliminary remarks by Sir Henry J. Gairdner from the chair, Professor Axel Reyn read a paper on the artificial light treatment of lupus and other forms of tuberculosis. He said that the creator of this light treatment was the late Professor Finsen; time would not allow all the different investigations on which Finsen based that treatment to be discussed, and Professor Reyn dealt only with the results of light treatment in different forms of surgical tuberculosis and tuberculosis of the skin. At the beginning of his experiments Finsen used the sun as a source of light, but it became clear that if light treatment was to be of any great value in northern countries it would be necessary to use artificial light. In further experiments Finsen showed that the ultra-violet rays had the strongest effect, and he gradually came to employ artificial light alone, for the carbon arc light contained far more ultra-violet rays than the sun, whose ultra-violet rays were absorbed by the atmosphere. Finsen died before he could finish his work on light-bath treatment, and it was left to others to carry out the experiments laid down by him. Bernhard and Rollier were the first to use the sun bath for surgical tuberculosis. Having seen the excellent results that Rollier obtained, he (Professor Reyn) decided to try light baths in treating lupus vulgaris and various forms of surgical tuberculosis. Professor Reyn then showed on the screen some very interesting cases of lupus and tuberculosis of glands which had been cured by artificial light baths. In referring to x-ray treatment for glands, he contended that in the great majority of cases nothing but bad results were obtained. In the discussion that followed, Dr. Sequeira (London) directed his remarks to the following points: First, he maintained that failure was often due to a faulty technique. Secondly, the attack should be a combined one—namely, local and general. Excision of a tuberculous lesion should be practised when it was in such a situation that a resulting scar did not matter, but for a scar on the face Finsen light was the ideal procedure. Dr. Sequeira then showed photographs

of cases treated by Finsen light in this country. He agreed with Professor Reyn that x-rays in dry lupus was a treatment to be deplored, and maintained that it could do nothing but harm. Professor Russ said that wave lengths of all radiation had been measured and that it was becoming possible to predict the effect of different rays on diseased parts. Wave lengths from 3,000 to 2,000 Angstrom units were easily absorbed by animal and vegetable tissue. No radiation up to 3,000 would penetrate one millimetre of skin. Wave lengths from 3,800 to 3,000 were a very important series. Those parts of the spectrum responsible for clinical improvements should be ascertained so as in future to concentrate on those particular rays. Sir St. Clair Thomson described his visit to the Finsen Institute, and his observations of the results obtained in tuberculosis of the larynx. In Copenhagen he heard that 50 per cent. of arrests had been secured, and he thought this very possible, as local measures in addition to the arc lamp baths were employed. He asked for further directions as to technique and precautions. Dr. J. M. Johnston mentioned two cases of painful laryngeal tuberculosis in which the carbon arc lamp was used with great relief to the larynx; there was, however, no change in the pulmonary physical signs. In his reply Professor Reyn said that the light treatment was better carried out in England than in any other country. He agreed with Dr. Sequeira that other local measures should be combined with light treatment.

Dr. J. Gravesen (Copenhagen), in opening a discussion on the present position of surgical treatment of pulmonary tuberculosis, said that the particular kind of surgical treatment he would discuss was based upon experiences with artificial pneumothorax, the principles of that method having put an end to all previous devices, such as incision with drainage of cavities, and excision of lobes. The results of pneumothorax treatment must be judged according to the anatomical and physiological possibility of full benefit from the treatment. In order to determine the actual results and to justify further methods in cases where the induction of pneumothorax was technically impossible, it was necessary to classify the cases with regard to the influence exerted by the presence of pleural adhesions. Such classification had been utilized in the largest series of cases published on this subject—namely, that of Saugman (Vejlebjerg Sanatorium, Denmark). Dr. Gravesen gave details showing how often adhesions made it difficult to obtain the full benefit of artificial pneumothorax, and what excellent results the treatment would give could the injurious influence of adhesions be removed. As a general indication for collapse treatment a case was considered suitable when no hope of lasting cure by ordinary sanatorium treatment or other special remedies could be brought about. Dr. Gravesen then discussed the treatment in various groups of cases. In those with complete or almost complete pneumothorax, but with localized adhesions, thoracoscopy with cauterization was practised. When artificial pneumothorax was impossible thoracoplasty should be performed, and two questions with regard to that operation were considered: (a) Should a partial or a complete thoracoplasty be done? and (b) Should the operation be performed in one, two, or more stages? In the discussion Mr. J. E. H. Roberts said it was not necessarily true that bad results were due to adhesions, but infection was more virulent in cases where adhesions were strongest. He had lately modified his views regarding the Jacobaeus operation for cauterizing adhesions. He believed that in many cases it was a good procedure, but in others the adhesions were so firm that thoracoplasty had to be performed. He urged the importance of careful preparation of a case to be subjected to thoracoplasty. He preferred not to rely on a local anaesthetic; gas and oxygen was the anaesthetic of choice. The after-treatment was as important a factor as the operation itself. The chest wall should be immobilized by strapping for at least ten days, and subsequently proper physical exercises should be practised to prevent scoliosis. Dr. Vere Pearson, in discussing the choice of patient for artificial pneumothorax, urged that a fair trial of sanatorium treatment

it calling. Reverence was not always paid by looking up to the light which no man could approach unto, as was known largely through the things. He had made, which He had imparted light and colour, mystery and duty, the majesty of order, and the skill of natural processes. The reverent man had reverence, not only for a Creator, but for created things. Here surely was something which belonged to the sphere both of those whom was addressing and of himself as a minister of the Church. It might well be that those whose task it was to each reverence were not always themselves the most reverent. Familiarity, habit, and contact with the sort of merely material aspects of life might deaden reverence those who should uphold it. Before the medical profession the knowledge of the human body lay open, a science themselves were beginning to discredit the original discovery. There were some who believed vitamins to be actual substances, while others—to whose views Dr. Elliot evidently inclined—considered them to be, not substances, but merely a balance between various factors. He went on to speak of the distinction between transmuting foods and energy-yielding foods, and described the work of Lavoisier on oxidation in the body, just as it took place in a furnace, and of Liebig, to whom the classification of foods into proteins, fats, and carbohydrates was due. Man, said the lecturer, was a parasite upon the green plant, just as truly as the green fly was a parasite upon the rose. He described nitrogen and its power, in some forms so innocent, in others so tremendously destructive, and in food, where its molecules could be taken apart and built up again into a new combination within the body, responsible largely for vitality. He showed how the body used iron as the machinery for taking oxygen from the air and conveying it to every tissue, also how necessary calcium was even in the repair of the smallest wound, how chlorine was handled by the soft tissues, and so on. He believed that the mineral elements in diet had received less attention than their important place deserved. One of the few things established as the result of a study of dietetics was that monotony in diet was dangerous, any the danger could not altogether be disregarded even in a civilization in which the chef had more resources than ever before; for our people lived very largely on imported food—this country spent about £500,000,000 a year on imported foodstuffs—and it might well be that these products were deficient in some vital principles. Fresh instincts of man might be depended upon to some extent as to diet, and the instincts of animals in the way of supplementing any deficiencies were often uncanonically correct. A pig kept for twenty days on a diet deficient in lime, when let out of its sty went straight to a heap of builder's lime and took its fill. In conclusion the lecturer uttered a warning against paying heed to anyone, medical man or other, who claimed to understand the process of nutrition. These things were still mysterious, and the man of science was holding up a candle in the night by which to discern only the extent of the things he did not know. The chair was taken by Dr. C. F. Routh, who, in thanking the lecturer, referred to the extent to which food, like dress, passed through phases of fashion, area necessarily limits the work done in Calisthenes and

upon a pork chop so that it rose up and became Plato the world would accept as a miracle. But what actually took place during digestion and assimilation was scarcely less mysterious. It was as wonderful as if a wizard were to turn the chairs and tables on the platform into members of Parliament. Assimilation, one of the key factors in living matter, was still a mysterious thing; so much so indeed that students of dietetics were constantly driven to explain it by the invention of new hypothetical substances which nobody had seen or isolated. He noticed that vitamins had now reached the stage of newspaper advertisement; it might be depended upon that the most recent of science it might be depended upon that the original discovery. There were some who believed vitamins to be actual substances, while others—to whose views Dr. Elliot evidently inclined—considered them to be, not substances, but merely a balance between various factors. He went on to speak of the distinction between transmuting foods and energy-yielding foods, and described the work of Lavoisier on oxidation in the body, just as it took place in a furnace, and of Liebig, to whom the classification of foods into proteins, fats, and carbohydrates was due. Man, said the lecturer, was a parasite upon the green plant, just as truly as the green fly was a parasite upon the rose. He described nitrogen and its power, in some forms so innocent, in others so tremendously destructive, and in food, where its molecules could be taken apart and built up again into a new combination within the body, responsible largely for vitality. He showed how the body used iron as the machinery for taking oxygen from the air and conveying it to every tissue, also how necessary calcium was even in the repair of the smallest wound, how chlorine was handled by the soft tissues, and so on. He believed that the mineral elements in diet had received less attention than their important place deserved. One of the few things established as the result of a study of dietetics was that monotony in diet was dangerous, any the danger could not altogether be disregarded even in a civilization in which the chef had more resources than ever before; for our people lived very largely on imported food—this country spent about £500,000,000 a year on imported foodstuffs—and it might well be that these products were deficient in some vital principles. Routh, who, in thanking the lecturer, referred to the extent to which food, like dress, passed through phases of fashion, area necessarily limits the work done in Calisthenes and

The Popular Lecture.

The Popular Lecture was delivered on Friday evening in the Examination Hall of the Municipal College by Dr. W. E. Elliot, M.C., M.P., Parliamentary Under Secretary of Health for Scotland, whose subject was "Food and Health." Those present were treated to an interesting exposition of some principles of dietetics, and carried away some good advice, the chief of which was, perhaps, in the words of the old music-hall song, "A little bit of what you fancy does you good." Captain Elliot took his audience in some pleasant excursions into the realms of fantasy, bringing home to them the wonders of the process of assimilation. Here were various substances used as foods, widely different from one another in their origin and composition, and all of them alien in structure from the flesh of human beings, yet when taken into the body they were convertible into human tissue. If a man could breathe

discussion of various points made by the author, in which Drs. Flemming, Wilkins, Featherstone, and Moore joined. Dr. Singleton, in turn, replied in detail to each of his critics. This paper was followed by one from Dr. A. L. Flemming (Bristol) on fatalities from anaesthetics, which was in turn criticized by Drs. McNamara, Singleton, and Mott. As time was pressing and there was still another paper to read, the President then called upon Dr. Flemming to reply. Dr. H. E. G. Boyle (London) next read a paper on anaesthesia by the gas-oxygen-ethanesal and the gas-oxygen-chloroform-ethanesal combinations, and illustrated the same by demonstrating his apparatus for the carrying out of these sequences. There being no time for discussion of this paper, Dr. Christopher Mayhew (Southsea) demonstrated a new apparatus of his own invention for the administration of warmed ether vapour, the chief advantages of which were, he claimed, its lightness and portability, the whole apparatus only weighing a little over a pound, and its warming cylinder being able to accommodate easily the whole of the rest of the apparatus when packed for travelling.

### THE PATHOLOGICAL MUSEUM.

The Pathological Museum contained a series of thirty-four separate sets of exhibits illustrating a great variety of pathological curiosities. Many of the specimens were used by the exhibitors for demonstrating subjects about which they spoke in the different sectional meetings, in the reports of which a record will be found of some of the exhibits displayed in the Museum. Other exhibits, not coming within the scope of subjects discussed in the sectional meetings, were explained in brief demonstrations in the afternoons.

On July 25th Dr. H. A. Miller gave an account of the effect of certain esters of unsaturated fatty acids in the tubercle bacillus when growing *in vitro*. The bacteria showed banding and beading appearances similar to those obtained by Sir Leonard Rogers with leprosy bacilli by treating them with chaulmoogra oil. He described experiments he had commenced on the treatment of guinea-pigs suffering from tuberculosis with these unsaturated fatty acids, the results of which had been encouraging. He used chiefly the ethyl ester of hydnocarpic acid, and also potassium linoleate and sodium morrhuate.

Sir Leonard Rogers described how, by first employing intravenous injections of the sodium salts of the fatty acids of chaulmoogra oil obtained from seeds of *Taraxiogenos kurzii*, he first produced reactions in leprosy tissue with the breaking down of acid-fast bacilli, followed by great improvement of the patient. Subcutaneous injections did not produce reactions in leprosy tissue, and were less effective than intravenous. He subsequently used sodium gynocardate and later olive oil, soya-bean, and castor oil, all with equally good results, and came to the conclusion that it was all a question of the unsaturated fatty acids. The ethyl esters were more convenient preparations, as they could be given intramuscularly. These unsaturated fatty acids probably acted by defatting the bacilli in the body. The addition of any of these substances increased the action of the ferment lipase, and treated cases had been shown to have increased lipase in the tissues. These substances probably acted, therefore, by increasing the activity and amount of lipase in the blood.

Dr. H. A. Harris demonstrated some beautiful specimens illustrating the relation between normal ossification and arterial distribution by the method of Spalteholz; also microscopic preparations of injected lymphatics by Hyrtl, and microscopic preparations of injected blood vessels by Thiersch. He showed specimens illustrating the bony changes in rickets, and radiograms showing the process of growth in the long bones of a child.

On July 26th Dr. Da Fano gave a demonstration on herpetic and epidemic encephalitis.

The first fourteen specimens were from the set from which the drawings illustrating the author's paper on herpetic meningo-encephalitis in rabbits were made. They clearly showed the intensity of the inflammation.

seen in the specimens were independent of the chosen for the transmission of the herpetic virus and characterized by widespread small-celled infiltrations, nerve cell degeneration, and diffuse proliferative phenomena of some of the fixed elements of the tissues (neuroglia cells, endothelia, adventitial cells, fibroblasts). In preparations from animals which either died or were a few days after inoculation the inflamed areas contained a number of polymorphonuclear leucocytes which were observed in epidemic encephalitis in man, but in preparations from animals which survived for longer periods foci of celled infiltration were found which, because of their position and situation, could not fail to remind one of described both in cases of lethargic encephalitis and in experimentally infected with the encephalitic virus. Specimens of this series showed the small granular structure which were termed by the author "herpetic minute bodies" and might perhaps be the virus itself.

Specimens 15 to 25 were from an acute case of encephalitis presumably epidemic. The case was particularly interesting because of its very rapid clinical course (death took thirty-six hours after the onset of symptoms), and because of intensity of the small-celled infiltrations affecting the white grey substance of the medulla oblongata, pons, mid-brain, thalamus, and certain parts of the cerebral cortex. In addition various haemorrhagic lesions were observed of a type unusual in epidemic encephalitis. The most important of these changes were shown in the specimens and corresponding drawings. One of them the demonstration was given of very small granules situated within polymorphocytes, and in every way similar to the "minute bodies" mentioned above.

Four specimens were from a chronic case of epidemic encephalitis in a child which was clinically investigated by Helen Ingleby. As shown by the microscopical preparations lesions were observed in this case on the whole similar to those described in subacute cases of the disease.

Within or next to elements of the lymphocytic type "minute bodies" were again noticed, characterized by the same morphological and tinctorial properties as those shown by Dr. Da Fano in some of the other specimens, and particularly in the last one prepared from the brain of a rabbit inoculated intracerebrally with an encephalitic virus sent from Stockholm by Professor C. Kling. The rabbit died about a month after inoculation and the histological examination of the brain showed a certain degree of congestion associated with a moderate perivascular and subependymal infiltration chiefly consisting of small lymphocytes. In certain regions (aræae rhinicae) many "minute bodies" were noticed either scattered in the nervous tissue or adherent to fragments of some protoplasmic material probably the remains of degenerated nerve cell.

Lieut.-Colonel Buchanan showed thirteen lantern slides and twelve mechanical models illustrating the mechanics of midwifery, and Mr. E. P. Bertwistle demonstrated a series of radiographic prints showing the characteristic contour of soft parts as well as bony tissues.

On Friday, July 27th, Wing Commander H. E. Whittingham, R.A.F.M.S., showed a series of slides and drawings illustrating the life history of *Phlebotomus papatasi*.

He said that the Royal Air Force Sandfly Fever Commission had shown that the virus of phlebotomus fever was transmitted from generation to generation of *Phlebotomus papatasi*. This might be effected in two ways—either it was transmitted by heredity or the larvae infected themselves in the breeding grounds by eating the excreta or the dead bodies of the parent flies. It followed that prophylactic measures against the fever must be directed upon the fly, the habits and habitats of which must be understood. The life history of *Phlebotomus papatasi* covered a period of about eight weeks, the exact time depending on conditions of temperature and humidity. The ovum in its maturation showed certain changes in its surface markings, and on the ninth day caudal bristles appeared. A few hours later the shell broke on the dorsum by the action of the egg-tooth. The larva emerged and entered upon its first instar, lasting six days and ending with the first moult. In all the larva passed through four instars of about six days each, and four moults, during which there occurred not only increase in size but developmental changes, characterizing each period. With the conclusion of the fourth instar the larva entered on the pupal stage, lasting about nine days, before the emergence of the imago. The wings of the newly hatched fly were crumpled and moist. Until these dried the young fly could only crawl. The recognition of this stage was most helpful in

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

## MEETING IN EDINBURGH.

of the Congress.

Insulin.

Immediately after the conclusion of the President's address Professor J. J. R. Macleod of Toronto gave a lecture to the Congress, the full text of which is published on page 165.

[illegible]

1. The Commission has been informed that the Government of the Republic of Armenia has taken measures to ensure the safety of the population in the event of a nuclear emergency. These measures include the establishment of a system of civil defense shelters, the organization of evacuation exercises, and the implementation of a system of early warning and communication.

This could be controlled by insulin, as could also the hyperglycaemia following puncture of the hind-brain. The lantern slides showed very strikingly the uniformity with which this occurred. An interesting series of observations had been made by Dr. Allen upon the effect produced by insulin administration upon the metabolism of proteins; it

Dr. F. G. Baxendale (Toronto) read a paper upon insulin, using that term to signify a substance isolated by chemical means similar to that which he had used in his paper upon the treatment of diabetes, and also upon the subject of the treatment of diabetes by insulin.

plasma had not been determined. Approximately one unit of plasma could be obtained from 30 cc. of normal rabbit plasma. Whether it was contained in the cells or created dogs. Whether it was contained in the cells or created dogs. Whether it was contained in the cells or created dogs.

small amounts of insulin. The urine of normal man contained such hypoglycaemic rabbits did not contain demonstrable it hypoglycaemic. The tissues (except the pancreas) of rabbits contained more insulin than that injected to render blood. The blood of a rabbit showing hypoglycaemic con-

Dr. Bañing suggested that this was due to some antibody, or to the insulin being involved in some complex, from which it was only liberated by the process of extraction. He then proceeded to speak of the factors influencing

the production of insulin. While in certain early stages of diabetes mellitus, on treatment with insulin, the patient may be kept in a relatively normal state of health. In certain advanced stages of diabetes mellitus, however, the patient may be kept in a relatively normal state of health only by the administration of large doses of insulin. In certain advanced stages of diabetes mellitus, however, the patient may be kept in a relatively normal state of health only by the administration of large doses of insulin.

the islets had suffered from prolonged overwork, and that sugar might stimulate insulin production. An attempt to demonstrate this action had been made as follows. Dogs were anaesthetized with ether for thirty minutes, and immediately afterwards received an intra-

ATTN: [REDACTED]

[illegible][illegible]

Mr. Adams asked, on July 23rd, whether in view of the fact that public vaccination was controlled by the Poor Law authorities, the Government had no responsibility for the prevention of small-pox, the

Minister of Health would take steps to transfer their powers to health authorities. The Minister of Health said that this suggestion was under consideration in connection with the Vaccination Act.

Mr. Mrps Davies asked under what act a medical officer of health had power to isolate compulsorily healthy people; and whether he would inquire into the fact that the medical officer of health threatened a perfectly healthy family from being isolated, in consequence of the family resistance to Gloucester where the laboratory was situated.

Mr. Chamberlain said that the average cost of treatment was £100, although patients were able to obtain insulin at a lower cost. He said that the diabetic patients were able to obtain insulin at a lower cost than the average cost of treatment. He said that the average cost of treatment was £100, although patients were able to obtain insulin at a lower cost. He said that the average cost of treatment was £100, although patients were able to obtain insulin at a lower cost.

[illegible]

The Minister of Health informed Mr. Adams, on July 25th, that the reorganisation of the registration service was being considered, and a suggestion that the registration should be transferred from the Poor Law to the health authorities should be borne in mind. Only four authorities in Scotland have taken exception to the transfer.

On the 12th of April 1907, the following letter was received from the Education Department (Singapore) in reference to the above mentioned matter:-

conscientious objection must apply to the vaccination officer for the form.

method are sufficient to counterbalance the disadvantages which its wholesale application would entail. That it has its uses in selected cases no one will deny.

The book is well got up, printed on good paper, and the illustrations are excellent, both from a practical and an artistic point of view. There is an adequate index and a foreword by William J. Mayo, M.D. Altogether the volume can be recommended to those who are interested in a new and growing department of the art of anaesthesia.

### ARROW POISONS.

*Die Pfeilgifte*,<sup>1</sup> by Dr. L. LEWIN, is an encyclopaedic account of the arrow poisons used throughout the world. The author deals with each continent in turn, and proceeds region by region to give an account of the arrow poisons used by hundreds of different tribes of savages.

In most cases the sources of the poison, the mode of preparation, and the pharmacological nature of the poison, are all given. Many hundreds of different poisons are dealt with in this manner. Needless to say, such a book could only have been written by a scholar with a wide knowledge of toxicology and ethnology. In addition, much of the information concerning the pharmacology of the poisons is original work by Dr. Lewin. In his preface he states that the book is the product of thirty years' work.

The book will appeal to several classes of persons. The preparation of arrow poisons is usually a carefully guarded secret, and in most parts of the world the more civilized races drastically discourage the preparation of poisoned arrows by the more primitive races; this policy increases the difficulty of obtaining any accurate information on the subject. Dr. Lewin's book should therefore be of considerable value to administrators and doctors in such countries as tropical Africa and the Malay Peninsula, where the use of poisoned arrows is particularly prevalent. The work is essentially one of reference, and for this reason we would suggest that it would be improved by fuller indexing; an author index in particular would be of value.

The first impression produced by the work is one of surprise that the use of poisoned arrows should be so prevalent and that there should be such an amazing number and variety of arrow poisons. Whilst the art of healing is represented amongst most savage tribes by a confused jumble of superstitions which at the best are useless, but usually actively harmful, yet in the art of destruction even the lowest savages show a most surprising degree of skill and ingenuity. A misanthropist might be tempted to moralize on this, but in fairness to the savages it must be remembered that poisoned arrows are used for hunting as well as for war, and the more primitive the weapons the more essential is poison if large animals are to be attacked. The skill shown by savages at the lowest stages of culture in discovering poisons for weapons is surprising all the same. Dr. Lewin considers it certain that poisoned weapons were used in Europe as early as the Magdalenian period. This is the more unexpected as Europe is not rich in poisonous plants; indeed, aconite and white hellebore are almost the only European plants likely to yield an effective arrow poison.

Arrow poisons reach their highest efficiency and complexity in the Malay Peninsula, and some of the poisons prepared there are made from as many as twenty constituents, the chief being the juice of the upas tree, so famous in fable. It is remarkable that all over the world glucosides allied to the digitalis series, and obtained from the most varied sources, are used as arrow poisons. In West Africa strophanthin is obtained from the climbing shrub strophanthus, while in South America the natives obtain a similar type of poison from the poison glands of toads. In the Malay Peninsula antiarin, a glucoside with an action like that of strophanthin, is obtained from the upas tree.

The complexity of the arrow poisons is, however, in many cases purposeless—for example, the bushmen of South-West Africa use a poison prepared chiefly from vegetables, and add to it snake venom, but since they subject the mixture to prolonged boiling to bring it to the right consistency the

snake venom must be rendered completely inert. Some tribes, however, know how to use toxalbumins such as snake venom for arrow poisons, for they drop the fresh poison on to the arrow and dry it in the sun. The bushmen of the Kalahari desert prepare a poison of great virulence from the larvae of a beetle (*Diamphida simplex*). Lewin found that one-quarter of the juice obtained from one larva, which weighed about two grains, sufficed to kill a dog. The bushmen, it is reported, kill lions with arrows poisoned in this way. In another part of the book the use of curare by the natives of South America is fully described, and physiologists will find a very complete description of the origin and constituents of the different varieties of this poison.

Dr. Lewin's book, dealing with all parts of the inhabited globe and with all periods of human history, contains a wonderfully interesting and full account of a very curious aspect of human culture. We believe it to be much the most complete treatise that has yet appeared on this subject.

### THE PRACTICE OF PREVENTIVE MEDICINE.

ALTHOUGH it was not until the beginning of the present century that any serious efforts were made in Canada in the direction of public health organization, it is already being realized in the Dominion that curative medicine and preventive medicine are very closely allied, and that the general practitioner must not be ignored in any public health scheme. Dr. J. G. FITZGERALD, professor of hygiene and preventive medicine in the University of Toronto, has written *An Introduction to the Practice of Preventive Medicine* with the object of outlining "some of the work of the physician who is to function on the preventive as well as the curative side of medicine." Although at the outset the practitioner may be alarmed at the sight of a volume of 800 odd pages which only outlines the subject with which it deals, he will not need to read very far before discovering that the author is an original thinker who is able to place facts and conclusions before his readers in an attractive and helpful manner. He looks forward to a time when everyone in the community will feel that an actual stigma attaches to one who has a preventable physical or mental disability and when the physician will be engaged to keep his patient well by routine examination, by supervision and advice. Nearly one-third of the volume is concerned with transmissible diseases, each being dealt with separately as regards its etiology, incidence, mode of transmission, and methods of control. With respect to the last, much sensible advice is given. For example, in the chapter on diphtheria the practitioner is reminded that he and not the laboratory makes the diagnosis, and that the bacteriological examination of a swab is only part of the evidence upon which a diagnosis should rest. Dr. Fitzgerald considers it highly desirable that the quantity of antitoxin which it is decided to administer should be given in a single dose, not in divided doses. He does not give much assistance in dealing with the difficulties connected with the control of diphtheria carriers. He admits that antitoxin is not a specific for the permanent relief of such carriers because it does not kill diphtheria bacilli but simply neutralizes any toxin they may produce. He considers that removal of diseased tonsils and of adenoids and the correction of deviations of the nasal septum may in many instances result in the disappearance of the germ because their lodging place has been removed or rendered unsuitable.

The control of measles in the mass is the despair of most public health officers; we turn, therefore, with interest to the advice tendered the family doctor who is attending individual cases. Stress is laid on the importance of the two earliest symptoms of measles—namely, rise of temperature and oedema of the conjunctiva. The temperature should be taken morning and evening, particularly on the eighth, ninth, and tenth days after exposure. The medical practitioner is urged to have clearly in mind the periods of incubation and infectivity of the disease and to remember that the

<sup>1</sup> *Die Pfeilgifte*: nach eigenen toxicologischen und ethnologischen Untersuchungen. By L. Lewin. Leipzig: J. A. Barth. 1923. (Med. 8vo, pp. xi+516; 75 figures, 1 plate.)

<sup>2</sup> *An Introduction to the Practice of Preventive Medicine*. By J. G. Fitzgerald, M.D., F.R.S.C., assisted by Peter Gillespie, M.Sc., M.E.I.C., and H. M. Lancaster, B.A.Sc. London: Henry Kimpton. 1923. (Roy. 8vo, pp. xx+826; 129 figures. 37s. 6d. net.)

he is not entirely familiar with medical science—for example, the sentence "Salimbeni and Gery carefully examined the tissues of a woman of 93, in which were found little cells coming from the lymphatic ganglion and the spleen" has a rather unusual sound. The work is beautifully illustrated, especially the chapter entitled "The old as viewed by the artists," including Rembrandt, Jordaens, von Lenbach, and Leonardo da Vinci's portrait of himself, which is described as that of a man who has seen, judged, and suffered everything, and no longer expects anything from anybody, the head of a lion overcome by old age.

Although the worst record is presented by dramatists, poets, and writers of romances, the author concludes that the best prospect of a long life is found among the intellectual and actively minded. The view of various philosophers and men of letters on the physical and moral states of old age, from Cicero to P. Faguet (obit 1919), are collected into a chapter which is followed by a detailed account of the structural changes. Old age is defined as a disease of the colloids, the protoplasm, and the interstitial tissues of the body. The mental characteristics and behaviour of old men are fully considered, with many references to well known historical personages, and to the views of Pierre Janet, Bergson, and Freud. The concluding chapter on the hygiene of old age contains much sage advice, recalling the directions of the late Sir Hermann Weber, who is duly quoted, on exercise, diet, and so forth. Sleep should last at least six hours and never more than eight, though bed may be utilized for work or reading; of books, the author's five favourites are the Bible, Plutarch's Lives, Horace, Montaigne, and Sainte-Beuve's *Lundis*. In conclusion, it may be said that Professor Lacassagne's essay is an interesting storehouse of information with a personal touch and a pleasant flavour of scholarly lore.

#### MORBID HISTOLOGY.

To the student commencing his practical studies in pathology, Dr. Donaldson's *Practical Morbid Histology*\* should prove very helpful. The author's plan has been to select a series of pathological lesions which shall include all those usually studied in the class of practical pathology, and to describe each lesion in language very similar to that which would be used in demonstrating an actual microscopic slide. The student, with his slide before him, will find in these descriptions all the important points to be recognized in the section. By marking those points which he has succeeded in identifying he will be relieved of the necessity of making his own notes, which his inexperience is apt to render defective; and he will thus have a record of what he has himself observed and of any details that the section has failed to illustrate. Later in his course of studies the student will find the book useful as a reminder of his previous observations and the particulars in which his knowledge needs supplementing.

Dr. Donaldson has wisely refrained from inserting any diagrams or illustrations. There can be no doubt that a good figure is of very great value in conveying a correct idea of a lesion, and many would consider it superior to any verbal description. But this would apply only to experienced microscopists; and it cannot be too strongly impressed on beginners that one of the principal objects of the practical class is to teach him how to use the microscope for the observation and interpretation of pathological changes. Illustrations tend rather to relieve him of the necessity of making an effort to this end, and are best dispensed with, at least in the earlier stages.

The author has gone somewhat beyond the scope indicated by the title of his book, in adding fairly full descriptions of the macroscopical appearances of the affected organs. It is not unusual in classes of practical histology to introduce specimens from the museum or *post-mortem* room; the addition of these descriptions is therefore justifiable, and the student is placed in a position to judge how far the changes observed in the microscopical sections are recognizable in the naked-eye preparations. Of less value,

perhaps, are the brief accounts of the pathogeny of the several diseases, which have been inserted with a view to forming a link with the textbooks of general pathology.

Forty pages are devoted to technical matters, including fixation, hardening, embedding in paraffin and celloidin, and staining. The instructions given are clear and full, and the staining methods recommended cover all that the student will require. A series of tables has been arranged in an appendix setting out the characteristics of the various worm parasites and their ova, together with brief notes regarding their life history. The book is one that will be welcomed alike by teachers and students.

#### TOMES'S "DENTAL ANATOMY."

THE eighth edition of Tomes's *Dental Anatomy*,<sup>9</sup> the standard textbook on the subject, has been edited by MARETT TIMS and BOWDLER HENRY. The book deals with both human and comparative anatomy and considerable additions have been made, especially to the description of the human teeth but the work remains as captivating and absorbing as I found it on first acquaintance many years ago. We are old then, and we still think that comparative dental anatomy was of no practical use to us, and we wonder what the dental student thinks now when the medical aspect of his profession is much more apprehended than it was thirty years ago. But Dr. Marett Tims is appealing not only to the dental student: he has in mind the anthropologist, and from this point of view we may suggest that an account of the common, or normal, variations of the human teeth might be included.

Remembering the preliminary report of the Royal Commission on Dental Caries, with its discussion of the importance and significance of organic matter in enamel, it is interesting to find the author roundly declaring that "there is no organic matter at all (in any noteworthy amount) in enamel"—and we are bound to say he seems us to establish his point.

That dentine is (in evolution) the oldest calcified tissue is a point that will surprise and interest many. The assertion that there would seem to be very little doubt that the cementum (of the neck of the tooth) is sensitive is a point we should absolutely contradict on clinical evidence. I should have liked a better description of the upper wisdom tooth of the Talgai skull than that "it is large but with the usual characteristics of an unerupted tooth," and we do not quite understand the statement (p. 127), "small round aggregations of pavement epithelium are met with at little depth or even embedded in the surface"—are these under the surface or exposed? But such faults are few and every student of odontology will be grateful to Dr. Marett Tims and Mr. Henry for this enlarged edition. The short account of human prehistoric remains—among which Galley Hill Man is included—adds greatly to the interest of the book.

#### NOTES ON BOOKS.

THE first edition of Dr. ABRAHAM LEVINSON'S beautifully illustrated and finely got up monograph on the *Cerebro-spinal Fluid in Health and Disease* was reviewed in our columns (1919, ii, 634). The call for a second edition<sup>10</sup> has given opportunity for revision and addition so that the volume contains 46 more pages, 8 more illustrations, and costs 7 more. The foaming of all pathological fluids on shaking, which lasts for half an hour or longer as compared with persistence for a few minutes only in normal fluids, is of greater size and longer duration in acute meningitis, has been shown by the author to be due to the increased protein content and not to carbon dioxide. Inencephalitis lethargica the type of cell in the cerebro-spinal fluid is inconstant, being in some cases a small lymphocyte, in others the polymorphonuclear leucocyte, but the author has found that there is often an increase in globulin without a corre-

<sup>10</sup> *Cerebro-spinal Fluid in Health and Disease*. By Abraham Levinson, B.S., M.D., North-Western University Medical School. Second edition. London: Henry Kimpton. 1923. (Med. 8vo, pp. 267; 5 coloured plates 61 figures. 25s. net.)

B.M.A. Reception for Ex-Imperial Graduates.

At the Edinburgh Graduation Ceremony on July 20th, when as reported last week over 200 graduates received the degree of M.B., an interesting innovation was introduced by the Edinburgh and Leith Division of the British Medical Association, which held a reception on Tuesday, July 17th, in the hall of the University Union. It was attended by about two-thirds of those about to graduate. The Chairman of the Division, accompanied by a number of members of the Association, received the guests. Copies of the *Handbook for Newly Qualified Medical Practitioners*, published by the Association, were handed to the guests on arrival. After tea the company was entertained with various musical items by Mr. Watt Jupp, violinist, and Mr. Patterson Lamb, pianist. An address of welcome into the medical profession was delivered by Professor Lorrain Smith, Dean of the Faculty of Medicine in Edinburgh University, who dealt with some of the difficulties that had to be faced by practitioners at the outset of a medical career, and emphasized the great advantages that accrued from the pursuit of other interests and hobbies, and from co-operation between members of the medical profession. Dr. James R. Drever, Scottish Medical Secretary of the British Medical Association, then gave an address dealing especially with the functions of the British Medical Association and the advantages to be gained both by the individual members and by the profession at large from making the membership as nearly as possible inclusive of everyone in active practice. A most enjoyable meeting terminated with a vote of thanks, proposed by the Chairman, Dr. John Stevens, to Professor Lorrain Smith for his address.

#### MEDICO-SOCIOLOGICAL SOCIETY OF EDINBURGH.

An excursion was made on July 7th by the members of the Medico-Sociological Society of Edinburgh to two ancient buildings of great importance in Scottish medical history. The society first proceeded to Torphichen Priory, some twenty miles west of Edinburgh. One of the members of the society stated that a colony of the Knights of the Order of St. John of Jerusalem had settled there in 1124, and had prospered greatly, inheriting all the Scottish property of the Templars on the suppression of the latter order in 1312. Throughout four centuries the Knights, both here and at almshouses and hospitals in other places, tended the sick poor. They had also tended the injured wayfarer, their most celebrated patient having been Edward I of England, when kicked by his horse at Falkirk in 1298. At the Reformation the Scottish Free-church had been disbanded, the Preceptor becoming a temporal Baron with the title of Lord Torphichen. The Norman remains in the Gothic building were inspected by the society, as also the stones of sanctuary, a privilege which the Priory had possessed. The party then proceeded to the House of Kippis in the immediate neighbourhood. Here Sir Robert Sibbald had been born and had spent a large part of his later life in medical practice. He had been responsible for obtaining the Charter of the Royal College of Physicians of Edinburgh in 1661 through the mediation of Sir Charles Scarburgh, who came to Scotland as physician to the Duke of York. In 1685 Sibbald, with Archibald Pitcairne and James Haller, had become the first professors of medicine in the University of Edinburgh. Sibbald and his friend Pitcairne had thus been the founders of a medical school in Edinburgh. The House of Kippis formed still a fine example of the forthright Scottish country home of the sixteenth century.

At the annual meeting of the representatives of branches of the Scottish Rural Workers' Approved Society in the ward of Management explained that the Society was now owing for its members, through the agency of the Scottish National Bazaar Association, dental treatment, dental and surgical appliances, and spectacles and other medical appliances. The secretary stated that these requests, particularly dental treatment, were now being requested by members on a considerable scale, that nearly £3,000 had been expended since these

#### Ireland.

Five Stars County Councils.

Many matters of medical interest were discussed at a recent meeting held in Dublin of the Irish County Councils General Council (Free State). The principal questions under consideration were health (including tuberculosis, maternity and child welfare), reconstruction, and unemployment, in which connection the demobilization of the army was discussed. A recommendation in the report of the Standing Committee on health matters was adopted, proposing that the qualifications of all candidates for surgical, medical, and veterinary appointments by Local Health and Poor Law Authorities be in accordance with regulations made by the Minister of Local Government, to include competitive examinations, practical as far as possible. The Committee also recommended the repeal of the *Medical Charities Acts*, and in substitution, the extension of medical benefits to insured persons and their dependants and the preparation of a register of those unable to contribute towards the cost of medical treatment, and the provision of such treatment for this class. The establishment of a medical service, paid by the State, and appointment of arrangements made by the State Health Authority. It was agreed that the forthcoming legislation should make the present permissive health legislation mandatory on local authorities.

The Committee also recommended that tuberculosis, both human and bovine, should be made compulsorily notifiable. It was agreed to recommend that compulsory powers be given to the Tuberculosis Medical Officer to isolate persons suffering from tuberculous diseases where he considered isolation essential in the interests of public health. Recommendations were also calling for effective inspection of cattle in respect of bovine tuberculosis; the application of the tuberculin test to milch cattle; the inspection of cowsheds, dairies, bakeries, and slaughterhouses; and of cowsheds, dairies, bakeries, and slaughterhouses; and for preventive treatment in the case of persons especially liable to contract tuberculous disease. It was agreed that there ought to be an abattoir in every city, town, and urban district with a population of 10,000 and over. Approval was given to the scheme for medical inspection and treatment of school children and enforcement of regulations against overcrowding.

#### Victoria.

[FROM OUR OWN CORRESPONDENT.]

#### The Melbourne Hospital.

The Melbourne Hospital, one of the clinical schools attached to the University of Melbourne, was re-erected on its present city site some twelve years ago. It was felt then as now that the retention of that site was a mistake. It is completely divorced from the University, has no possibility of extension on its restricted area of five acres, is everywhere surrounded by city property, and in some respects, particularly its out-patient department, is out of date. There has, therefore, been again raised the question of re-erecting the hospital on what is known as the Horse Market site. This site covers over sixteen acres, is in the closest proximity to the Medical School, is on high-lying land with an abundance of fresh air, has large possibilities of extension, and could be made to serve a much larger area of population than at present. The advantages

sterilization of their instruments, aseptic methods, were prophylactic measures against bacterial infection. It sounded like heresy, but it might be possible for a surgeon not aseptically efficient to vaccinate the patient against the few microbes he was likely to introduce. It might be heresy, but it was intellectually sound. There were certain cases they could not take precautions with, and the only way here was to raise the patient's resistance. Such operations were avulsion of teeth and excision of tonsils. A great many cancers came to the surgeon already infected with streptococci and staphylococci. He believed that the swollen arms seen after breast operation were due to streptococcal infection. What was the treatment of bacterial disease? Lister thought bacteria could be killed in the tissues by antiseptics. This was impossible and unsuccessful. The last thing an antiseptic would attack was the highly resistant microbe; an antiseptic would attack any other prey before a microbe. If they had organisms in a test tube and put in an antiseptic the chemical would attack the bacteria because it had nothing else to attack. The case was very different when an antiseptic was added to bacteria in an albuminous fluid. It went then for the fluid and not for the bacteria. Similarly it went for blood rather than the microbe in the blood. They could get better cultures from blood containing bacteria to which antiseptics had been added than from similar blood without antiseptics. The addition of antiseptics into blood or tissues was a foredoomed failure. He wished to use certain new words. "Prophylaxis" meant to take protective precautions in advance. He would shorten this to "phylaxis." Hence the phylactic power of the blood was the power the blood had of taking care of itself. "Ec-phylaxis" meant a part into which the body fluids did not penetrate, as an abscess cavity—an ec-phylactic focus. "Kata-phylaxis" meant the bringing of the protective powers of the body to the part where they were needed. Surgical methods of producing kata-phylaxis were the opening of an abscess, the application of a fomentation or 5 per cent. salt solution. The last new word was "epi-phylaxis." If they could not get what they wanted by the blood, by kata-phylaxis, etc., then they might resort to epi-phylactic measures. They would never be able to do away with their operations, but they could increase resistance by epi-phylactic means. There might be a time when the patient's blood gave no immunizing response to vaccines; then if the abscess were opened and immediately another sample of blood taken an immunizing dose might be given. Not every patient nor a patient in every condition could respond. If the patient's leucocytes were so poisoned that they could not respond, the first thing in treatment was to get rid of the microbes. For local infections a proper dose of a proper vaccine must be given. Pasteur said give a living vaccine; the speaker and others said give a dead one. Next arose the question of an autogenous or a stock vaccine. The more he considered this question the more difficult did it become to make out a case for the autogenous vaccine. A man with sixty furuncles might have a separate organism in each! There was justification for the autogenous vaccine if there were not a suitable vaccine in stock. With regard to dose it was most important to apply the right quantity. The only way to judge the right dose was to test the response of the blood. They could not possibly go by clinical symptoms. Vaccine therapy did a great deal if the right dose were given and the patient were capable of response. There were cases where the patient was so ill that one hesitated to give a vaccine. Would a vaccine to an already intoxicated system do good or just intoxicate more? In these cases the blood must be tested. If there was no response in the leucocytes it was useless to try vaccination unless the surgeon could come in first and get rid of the poison. Immunotransfusion was the correct treatment in these cases. The normal and slightly ill man could give active immunization, but the graver cases needed passive immunization—serum therapy. In hospital the relatives should be warned, a compatible and willing man taken and inoculated with a suitable vaccine. In two or three hours the blood was drawn off, defibrinated, and 500 c.cm. introduced. Citrated blood should not be used since it pulled down the power of the leucocytes. It should be remembered that vaccino-

therapy was not applicable to all diseases. The patient might be too ill for this treatment.

Dr. ALEXANDRE ZAWADZI (Varsovie) advocated the use of autogenous vaccines in septic cases and especially in cases of calculous cholecystitis. Vaccination was a great help to surgery in such patients. The operation ought to be considered as a first vaccination with living microbes. It should not be thought, however, that vaccino-therapy would help a case in which there was no vital resistance left. In especially acute infections it might be wise to vaccinate with living organisms, after the manner of Besredka. In cases where it was impossible to obtain microbes for culture purposes he had found that injections of sterilized milk or fresh white of egg helped greatly.

Dr. MAYER (Brussels) pointed out that vaccino-therapy helped, but should never be taken to replace surgery.

Dr. LECLEERCQ (Morristown, New Jersey) and Dr. ZAHNADNICKY (Prague) also spoke.

#### OPERATIVE SHOCK.

Dr. CHILE of Cleveland, U.S.A., opened the discussion by elaborating a theory that men and animals were electro-chemical mechanisms to whom the laws of chemistry and physics might be applied in interpreting the action of therapeutic agents and measures. Each living cell consisted of two parts—the nucleus and the cell body—separated from each other by a selective semi-permeable membrane. The nucleus and body could not best be stained by the same medium, the one taking most successfully an acid stain, the other an alkali. The content of each, in the main, consisted of colloidal solutions. Two colloids of different reactions, separated from each other by a semi-permeable membrane, constituted an electric cell. Each cell of the organism was therefore a true electro-chemical unit—an electric cell. Since all organs and tissues of the body were multiples of these ultimate units, then each organ and tissue must be an electro-chemical mechanism, as must the whole organism. Careful measurements of the electrical conductivity of organs under varying conditions indicated that the first effect of stimulation within the organism was a slight decrease in the conductivity of the liver, followed by a rapid continuous rise in that organ as the state of exhaustion approached; a slight and prompt increase in the conductivity of the cerebellum followed by a gradual continuous fall; a relatively slower increase in the conductivity of the cerebrum followed by a gradual continuous decrease. In intracellular histological changes following excitation and exhaustion were paralleled by changes in electrical conductivity. Changes in the temperature of organs bore due relation to these facts. For instance, motor activity either voluntary or produced by direct electrical stimulation of a nerve, was accompanied by rapid alteration in the temperature of the brain and liver corresponding to phases of muscular activity—these alterations, however, being in opposite directions. Water was essential to the activity of the cell. It was the only medium in which a colloidal system could be established; it had greater catalytic power than any other substance, and was a chemical activator; it had also a greater specific heat than any other substance, and was a non-conductor of electricity. Before oxygen became available for use in the cell it must be dissolved in water. Oxygen the "acid-maker," was also essential. Oxidation produced acids, and these acids produced the essential alterations in the difference of potential between the nucleus and the cell body, and probably between parts within the cytoplasm, as the result of which accumulations of acid and an adaptive discharge of energy was provided. Water carried the oxygen in solution to the cells, dissolved the acid by products of oxidation and bore them away from the cells. Thus it constantly restored the acid-alkali balance, which was as constantly altered by the acidulating oxidation. In accordance with the electro-chemical conception water an oxygen in a vital and inseparable relationship made possible the electric variations within the cells whose manifestations constituted life.

Since electricity flowed from a higher to a lower potential, and since oxidation in the brain was the highest, the

meridian of life has passed, a yearly intravenous injection of parastibic, such as a preparation of arsenic and mercury. I have yet to hear of a syphilitic, who has undergone salvarsan mercurial treatment, developing cancer, from which I firmly believe he is immune. Once the cancer cell has appeared the surgeon's knife is, and always will be, the only remedy.

It will be difficult, almost impossible, to prove my contention. There will be no immediate and brilliant results. To my way of thinking we are more likely to get better results in the prevention of cancer by medicinal means than in its cure.—I am, etc.,

J. THOMSON SHIMLAW.  
Thornhill, Wigan, July 25th.

# ENVIRONMENT AND INTELLIGENCE.

Sir,—In your issue of April 14th, on page 64, under the heading "Environment and Intelligence," you quote from a report of the Medical Research Council as follows: "That progressive improvement in home conditions may be expected to react favourably, not only on the health, but also on the intelligence of school children." That the more intelligent children are better cared for is beyond question, but it by no means follows that by improving domestic conditions we shall improve the intelligence of those living under them; indeed, I am convinced that this would not be the case.

Nothing is so hereditary as intelligence, and those of defective intelligence will tend constantly to gravitate towards the lowest stratum of society—in which drink and disease are unremotely carrying on their task of the elimination of the intellectually unfit.

Last year my nurses classified the homes of hundreds of cases of mental and physical defect into three grades—the "A," "B," and "C" grades. "A" grade homes being "good," "B" grade "fair," and the "C" grade "bad." Obviously such a classification must be arbitrary, but those put in Grade "C" were altogether undesirable environment for young human beings. In Grade "A" were put 23 per cent., in Grade "B" 69 per cent., and in Grade "C" 8 per cent. Of the cases of mental defect investigated 58.53 per cent. came from the 8 per cent. which constituted the "bad" homes. These homes are made and kept by the parents who manifest the characteristics of mental defect—namely,

(a) The inability to plan their lives to ensure a reasonable standard of comfort.

(b) The inability to resist suggestions—to say "No, thank you," to excess of alcohol, or to deny themselves sexual pleasures—resulting in alcoholism and venereal diseases.

(c) The inability to grasp an abstract idea: and "where there is no vision the people perish."

(d) The inability to persist in any undertaking. This want of persistence is a marked characteristic of primitive races and of mental defectives.

In the State schools of New Zealand children of all classes are educated, and such schools reflect very fairly the average of the population. The private schools are, on the other hand, on the whole a selected class of children from families which for various reasons prefer to pay for their children's education. Presumably the tendency to demand defect would be approximately the same as in the children attending the State schools, yet the number of perfect sets of teeth varies considerably.

Of 197 children examined at P. School 11 (that is, 5.5 per cent.) had teeth free from caries or extractions.

Of 126 children examined at H. N. School 5 (3.99 per cent.) had such teeth.

Of 28 children examined at a private school in the same district and drawn from the same population but selected by the fact that a small weekly sum is paid for the course of instruction, 6 (21.4 per cent.) had such teeth.

The condition of the teeth is a better criterion of home conditions than clothing, as it can only be affected by persistent and intelligent parental care. Instead, therefore, of assuming that either good clothing or good teeth cause high intelligence we must conclude, I think, that the parents of intelligent children, being themselves intelligent, will exercise such care and foresight in the upbringing of their offspring that a good home, suitable clothing, and

sound dental and physical health will result. I am quite prepared to admit that dissolute and alcoholic parents of good intelligence may beget children of low intelligence as a consequence of their excess and diseases, thus starting a new "vicious circle" of drink, poverty, and mental defect, to carry their families down the rapid incline to extinction; but that the consequence of the effects of the poisons (alcohol, or the toxins of syphilis or tubercle) on the reproductive cells of the parents, and not of environment, is I am, etc.,

—I am, etc.,

ALFRED CLARK, F.R.C.S., Ed.

# THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

Sir,—Dr. V. St. John Croley (British Medical Journal, July 21st) suggests that the most effective method of propaganda in favour of vaccination would be by means of illustrated posters depicting the horrors of small-pox—of the more ghastly looking the better." I wish to point out that the present time is singularly inopportune for propaganda of this character. No doubt, photographs of such cases of small-pox as he has in mind are in existence (I could furnish him with some myself), but they certainly would not be a fair representation of the type of small-pox which is prevailing to-day and about which the present scare is being raised and apart from which this country is so remarkably free from the disease and has been for many years. The present "atavism" strain of small-pox is so extraordinarily benign in its character that even in unvaccinated persons the "horrors" Dr. Croley wishes to depict are practically unknown. A fair description of the average case occurring, say, at Gloucester would be "a mild attack of influenza followed by an eruption of pimples and free from complications and sequelae." Two or three days in bed during the prodromal stage is usually all the real illness that the patient suffers from. No doubt there is a small proportion of cases which are somewhat more severe, but secondary fever is quite exceptional and it is very rare for the patient to be "pitted." Indeed, at the end of a fortnight the skin is frequently quite clear. Moreover, eye complications, even in unvaccinated children, are almost unknown.

In the interests of veracity it is most desirable that medical men should avoid even the semblance of exaggeration in their advocacy of vaccination. We all deplore the exaggerations of the antivaccinists; let us be very careful not to be guilty of the same fault. Is not the case for vaccination strong enough without being bolstered up by any doubtful methods?

Unfortunately, the lay press, in its anxiety to help the cause of vaccination, often makes the most exaggerated claims and loose statements. There have been many glaring examples of this during the past few weeks. Even the medical press is not quite blameless. Let me quote one instance: Last week an important medical journal published a photograph of a woman with a thick small-pox eruption, and wrote over it: "A case of 'mild small-pox' as at present prevalent in Gloucestershire." In view of the fact that the case in question was one of the very few severe cases which have hitherto occurred at Gloucester, such a statement is certainly misleading.

May I also suggest the desirability of medical men refraining from prophesying evil as the necessary consequence of not taking medical advice? Prophesy is proverbially dangerous, but in connection with a controversial question like vaccination it is especially so. Medical prophecy in connection with this question has so often failed to come true that it tends to bring discredit upon the profession and certainly reduces the value of our advice on other questions. How often have we reiterated that if vaccination had been neglected the result would be disastrous and terrible retribution would fall upon the defenceless unvaccinated children. The experience of Leicester in 1904 (207) does not seem to mention Nottingham and

as the heart was properly supplied with blood. With regard to the vasomotor mechanism, Malcolm and others had asserted that the vessels were actually contracted during shock. All evidence supported this probability. Many, however, had shown that when shock was established the blood volume in active circulation was reduced. But why was it reduced? Cannon had called it "the problem of the lost blood." Where was it—in the splanchnic area or the capillaries? The practical surgeon said that it was not in the splanchnic vessels, which he knew were contracted during deep shock. In this condition the capillary blood count might exceed the venous by 2,000,000 corpuscles per cubic millimetre. There was therefore a capillary stagnation of the blood. Respiratory, motor, and sensory disturbances during shock were all accounted for by the low arterial pressure. Nervous causes, the influence of the absorption of toxic products, cold, the internal secretions, anaesthesia, haemorrhage, and sepsis, all might play their part in producing this condition. From whatever cause the lowering of the blood pressure came the effect of the change was to set in motion a series of events ultimately leading to a derangement of the body metabolism. There was necessarily a deficient oxygenation of the body tissues and a low capillary stasis. Here a vicious circle began, for capillary stasis resulted in a deficient oxygenation of the tissues, while this in turn aggravated the capillary delay, and it was an obvious consequence that a further fall of blood pressure should result. There followed, as a symptom of a deficient capillary circulation, a fall of the alkali reserve of the blood. Treatment should follow well known lines. The possibility of haemorrhage and sepsis simulating true shock should not be forgotten; the patient must be kept warm. Fluid would help to maintain the blood pressure. Sleep was all-important, though the extent to which morphine should be pushed was very debatable. Adrenaline, strychnine, alcohol, and pituitary extract were of little if any use. Digitalis and camphor were useful as temporary stimulants; oxygen should be given if there was cyanosis; it also relieved restlessness and air-hunger. Glucose and sodium bicarbonate were of value if acidosis was present. Transfusion of blood was excellent, of colloidal solutions useful, but the value of saline solutions was probably very small. Based upon the researches of Abel, Rous, and Turner, the injection of blood corpuscles preserved in a citrate-dextrin solution might be employed. A solution could be kept on ice as long as three weeks. Results so far had been encouraging.

Dr. VICTOR PAUCHET of Paris said that the transfusion of pure blood was on physiological grounds superior to the transfusion of citrated blood. But the latter was easier to perform and could in consequence be more widely applied. The blood was obtained from the donor in an atmosphere of oxygen, and thus venous became transformed into arterial blood, whose action was especially efficacious in the treatment of shock. Its injection after the method of Bécart was a most excellent weapon against the pathological effects of the condition. By it there resulted a rise of blood pressure not tending to subside as after normal saline injections. Blood, moreover, unlike saline, did not filter through the capillary walls. By it also acidosis was neutralized and oxygen carried to the central nervous system and the endocrine glands. The transfusion of citrated blood was already a wonderful discovery, and he considered that the transfusion of pure oxygenated blood was a further improvement. The reason why blood transfusion, the ideal treatment for shock, had not been more widely used was due to the lack of systematic organization in most hospitals. Every unit—surgical, gynaecological, or medical—ought to be provided with a special service, with trained attendants and latest instrumentation, so that blood transfusion could be as easily carried out as the injection of normal saline.

Dr. UFFREDUZZI (Turin), Dr. JIRASECK (Prague), and Dr. MAYER (Brussels) also spoke briefly.

#### PITUITARY SURGERY BY A NEW METHOD.

Mr. A. K. HENRY read a paper on a new method in pituitary surgery. He showed an instrument which he had devised, which, used in conjunction with intermittent radio-

graphic control, allowed the pituitary fossa to be entered with mathematical precision by the trans-sphenoidal route. The instrument consisted of the following parts: Two intranasal bars lay one on either side of the nasal septum. These bars bent vertically down in front of the lips and carried a pivoted rod with a terminal cap which entered the mouth. This cap, protected by rubber, pressed against the hard palate, when a screw approximated the rod to the vertical bars; this kept the instrument fixed and stable. He was indebted for this effective device to Dr. Dorothy K. Milne-Henry.

To the vertical rods were attached two plates, and between them was pivoted a tube which could be aimed at the pituitary by means of a screw. The squared end of the tube carried a vernier which travelled over a scale attached to one of the plates and enabled the inclination of the tube to be . . . . . The aim was controlled and corrected . . . . . Resection of the nasal septum allowed instruments to be introduced submucously to the face of the sphenoidal sinus. The method admitted the use of any manipulation which could be carried out through a tube, and instruments resembling those used with an operating cystoscope were available. It was a simple matter to leave a radium tube within the sella. The use of the instrument removed the difficulties which made the trans-sphenoidal route formidable. Earlier diagnosis would still further increase its utility.

His first experience with the instrument in the living after a year's experimental work on the cadaver was not, however, in a case of pituitary disease, but in an operation for sphenoidal sinusitis, performed with Mr. J. Stafford Johnson, in which it gave excellent results. He had since used it in two operations upon a case of hypopituitarism with irregular hemianopia, followed by blindness, in which radiography appeared to show a greatly enlarged sella.

At the first operation a part of the pituitary was removed easily, and without any incident except the occurrence of a polyuria of 5 litres daily for three days. Six weeks later, as the blindness was unrelieved, a second operation was performed, and a second moiety of gland was removed. This intervention was followed by death in eight hours.

Autopsy revealed the fact that the hypopituitarism was due to an occlusion of the aqueduct of Sylvius causing hydrocephalus, and giving rise to a rarefaction of the bones which, in the radiograph, had simulated a deep excavation of the sella. Only a very small fragment of pituitary substance remained. Death was due to diffuse choroida haemorrhage caused by the sudden relief of pressure following a small tear in the third ventricle, which had bulged down into the almost empty sella. This tear gave rise to a gush of cerebro-spinal fluid, which, at the time was thought to come from a cyst. These operations were performed before ventriculography became current practice.

The point emphasized was that at the first operation the greater part of a small compressed gland, offering an exceptionally small mark for the instrument, was removed without ill result.

Failure in this case was due to the diagnosis, and not to the instrument. The opening made by it was as precisely accurate as if drilled from within under direct vision.

In conclusion he cited the following passage: "We have sacrificed opportunities of progress in the anatomy, physiology, and surgery of the brain by too ready acquiescence in the assumption that we must remain dependent on the visual sense for every species of intracranial operation."

THE second International Congress of Urology will be held in Rome from April 23rd to 27th, 1924, when the following subjects will be discussed: Renal innervation, introduced by Dr. Ambard of Strasbourg, Professor J. S. B. Stopford and Mr. J. B. McAlpine of Manchester, and Dr. Zoia of Pavia vaccine treatment of urinary diseases, introduced by Drs. Røvsing and Wulff of Copenhagen, Dr. L. S. Dudgeon of London, Dr. Noguès of Paris, and Dr. Pirondini of Rome remote sequelae of operations for renal calculus, introduced by Drs. Brongersma of Amsterdam, Cifuentes of Madrid, and Tardo of Palermo; recent progress in urology. The last subject has been proposed by the British and American delegates, but the speakers have not yet been selected. Further information can be obtained from the general secretary, Professor A. L. Bonanome, via dei Gracchi, 124, Rome.

indefinite causation of illness is evident, and tuberculosis as a differential factor in the beginning of disease in a fair proportion of cases is ignored.

The report of our M.O.H., Dr. J. J. Jervis, shows that the Registrar's deaths from bronchitis has fallen in Leeds from 738 in 1915 to 556 in 1921; whilst the fall for death records of over 550 contacts is personally examined repeatedly at periodic intervals during three and a half years on symptomatic grounds reported by our trained nurse-visitors, 55 per cent. were clinically tuberculous as confirmed by present history. When the definite cases were classified as years gave the high percentage of 67 and children a percentage of 15. Diagnosis in children is admittedly more difficult in the incipient stage, and the estimate, therefore, from the above considerations I submit: (1) That in the interest of a rigorous tuberculosis campaign to the advantage of the patient, all cases of tuberculosis, definite or suspicious, should be notified by all practitioners, whether in private practice or in institutions.

(2) Insured cases certified as bronchitis, anaemia, debility, gastritis for over three months should be investigated by the Regional Medical Officer and the differential diagnosis of tuberculosis ascertained. Notification of positive cases and examination of other suspicious contacts could thus be effected.

(3) All contacts with symptomatic history should be periodically examined by an experienced member of the staff whose diagnostic skill is recognized locally and definite cases referred to own doctors and notification enforced.

(4) For notification to be effective it is imperative clinical ability and diagnostic skill should be the paramount qualification for tuberculosis work. The system followed in Birmingham, Sheffield, and partly in Leeds of officers doing dispensary, sanatorium, and domiciliary consultation work is excellent, and wherever possible should be encouraged by the Ministry. By that means after-history will be known and there will be no squabble over diagnosis.—I am, etc.,

Z. P. FERNANDEZ, B.A., M.D.,  
Leeds City Tuberculosis Department.

July 22nd.

Sir,—While the facts in Professor A. J. Clark's lecture on the experimental basis of the condensation therapy (Journ. July 14th, p. 53) are beyond dispute the conclusions drawn are not in accord with clinical experience. Polyphagular therapy has succeeded in some cases where other remedies have proved useless. In my hospital and private practice I have for several years had occasion to treat cases of arthritis occurring in women at or about the climacteric period of life.

The history and type of patient vary considerably from the acute infective polyarthralgia cases. The patient has always been well and active, looks healthy and well nourished in early cases. She has usually passed the climacteric, and her only complaint is the joint affection. The onset is insidious and the condition tends to progress and in many cases there is great deformity and disability. The joints affected are more commonly the metacarpophalangeal and the metatarsophalangeal (usually the first and second) and the knees.

It is difficult to find any definite infective foci but of course difficult to exclude the possibility of some slight infection. It has been recognized for some time that there is probably some endocrine deficiency or faulty metabolism in these cases. Treatment in the past has been difficult and disappointing. Vaccines are of little use, stimulating and eliminative measures are certainly helpful, and in some cases thyroid has been of undoubted efficacy.

For some time I have been using a polyphagular preparation in these cases and it has certainly proved most useful. As the mortality of this form of arthritis is almost nil definite evidence is lacking as to the exact condition of the ductless glands in these cases, but we know that the

Sir,—From the correspondence on ether versus chloroform reference to the experimental work of Levy with chloroform, Lewis's opinion of Levy's research—"His work upon death subject is a landmark in the history of research upon death under chloroform." Quite briefly stated, Levy's two main conclusions are as follows:

(1) Death during administration of chloroform to cats is almost always due to *ventricular* fibrillation, which is also the case of death in the majority of chloroform fatalities in the human subject. (2) These fatalities are especially liable to occur "in the induction stages or at other periods" when the saturation of blood with chloroform is relatively low.

The latter conclusion, based upon very careful and convincing research, would seem to take the wind out of the sails of those who strongly advocate the safety of chloroform "given with a light hand."—I am, etc.,

Headings, July 22nd.  
Gordon Lambert.

Sir,—I read with interest the article of Dr. Jonathan Meakin, M.D., on "Dyspnoea in Cardio-vascular Disease" (B.M.J., 23.6.23).

There are many details of his re Cardiac Failure, "there is a sharp decline in the output of the ventricle per beat; instead of expelling 100 c.c. per beat the ventricle may only expel 15 c.c. to 25 c.c. per beat; in such circumstances the ventricle on each contraction does not completely empty itself and consequently there is a residue of blood left in the ventricle at the beginning of diastole. As the amount of this residue increases so the symptoms of Cardiac Failure become more pronounced." I believe Dr. Meakin is mistaken in these views. In a booklet I brought out ("Original Observations on Cardiac Disease," 1/3d., Cornish Bros., Birm.), in April, 1920, I there gave an account of what I term "Fractionated Heart Contractions." If I might use a simile I can explain Fractionated Heart Contractions clearly and briefly—Imagine a ladder with 20 rungs (number 1, 2, 3, 4, 5, etc. from the bottom to the top) placed at the side of a house, and a bucket (manipulated by a rope and pulley) hoisted from the bottom to the top.

Now suppose the bucket is hoisted to the top rung (number 20) and the bucket is lacking as to the exact condition of the ductless glands in these cases, but we know that the

operation and therapy often atrophy at that time and that substitution therapy is indicated. If results are favourable there is a great deal of experimental work to be done to confirm the facts.

Leonard Williams, in his paper in the Journal of June 19th, refers to arthritis as a deficiency disease, due to exhaustion of the endocrine glands as the result of toxæmia and lack of vitamins in the diet.

The whole subject is complex and it is only necessary to read the report of the discussion on rheumatoid arthritis at the meeting of the Royal Society of Medicine on April 23rd to realize how vague are our ideas as to the cause of these conditions, and although polyphagular therapy does not get to the root of the matter it is of undoubted utility in combination with other treatment.—I am, etc.,

merely an instructive medical conference, but a series of charming entertainments. Chief among the evening functions were the President's reception on Tuesday, the Mayor's reception on Wednesday, the Divisional reception on Thursday, and the Mayor's ball on Friday. The hours of daylight were equally full of festivity for those who could tear themselves away from sterner business. Each day had its programme of garden parties or visits of inspection to naval establishments and kindred objects of interest, while on Saturday no fewer than seven separate excursions were in progress. For the excellence and variety of these many trips the Association owes a debt of gratitude to its hosts. Some acknowledgement to those who co-operated so generously in entertaining members and their women-folk during the week was made at the Annual Dinner and at the end of the Representative Meeting, as recorded in the SUPPLEMENT at pages 81 and 84. Further appreciation of individual hospitality and service is offered in a note on the excursions at page 87. From all quarters we have heard praise for the local arrangements.

### THE HORMONE OF THE PANCREAS: INSULIN.

THE numerous questions raised by the isolation of insulin were discussed both in the Section of Medicine at the Annual Meeting of the British Medical Association and at the International Physiological Congress at Edinburgh. The latter body, whose members are more accustomed to lecture than to listen to lectures, gave up its first session to Professor Macleod, who reviewed the present situation in the lecture printed in full this week (p. 165). He began by relating the story of the earlier attempts to obtain the hormone of the pancreas; it is not only an interesting chapter in the history of physiology, but it is helpful to the practitioner of medicine by the strong impression it produces of the special characters of this hormone, its delicacy, and its potency.

The two great merits of the researches carried on at Toronto seem to us to be, first, the courage and enterprise shown by Dr. Banting in attacking the subject again. He took advantage of an old observation that obstruction of the ducts of the pancreas was followed by degeneration of the cells of the acini by which the pancreatic juice is secreted, while the islets of Langerhans remained little if at all affected. Physiologists had long been confident that the pancreas produced a hormone, and that it was formed in the islets of Langerhans; so confident indeed were they that Sir E. Sharpey Schafer suggested the name "insulin" for the hormone. The difficulty was that when an extract of the whole pancreas was made the hormone was destroyed by the trypsin-producing cells. Many physiologists attempted to overcome this difficulty, but they were not able to obtain convincing evidence that an antidiabetic hormone did actually exist in the pancreas. It is to the enduring credit of Banting and Best that by experiments of a different type from those of their predecessors they established its existence. The other great merit of the Toronto experimenters was, we take it, that they unravelled the meaning of the convulsions which ensue in an animal rendered diabetic by excision of the pancreas when insulin is injected. Several earlier experimenters seem to have been on the verge of the discovery of insulin, but were deflected by the occurrence of symptoms considered to be toxic but which it is now seen were probably due to hypoglycaemia.

The Toronto observations showed that convulsions are in fact produced by a deficiency of sugar in the blood, and can be arrested by the injection of glucose; apparently the brain cannot function without a sufficient amount of sugar in the blood which reaches it.

Knowledge of the way in which insulin produces a lowering of the sugar in the blood, both in health and in diabetes, is as yet imperfect. It seems to have been conclusively established by animal experiments that insulin does not stimulate the destruction of sugar within the blood itself. Its action is extravascular, and it seems probable that it produces, so to say, a kind of hunger of the tissue cells, which pick out the sugar in the blood. In this connexion it must be remembered that insulin has an important action on the metabolism of fat in diabetic animals. Lipaemia may occur in advanced diabetes as well as acetonuria, and in a dog removal of the pancreas is followed by the presence of excessive quantities of fat in the blood and the liver. In some way the migration of fat in the body becomes abnormal, and its final oxidation is seriously interfered with. When insulin is given to the animal acetonuria very promptly disappears, the blood fat apparently more slowly. As the amount of fat declines that of glycogen in the liver increases; that is to say, there is a movement towards normal.

Again, the history of the subject makes it improbable that one of the questions asked by Sir Thomas Horder in opening the discussion on insulin in the Section of Medicine at Portsmouth can ever be answered in the affirmative. His question was whether it is likely that it will become possible to administer insulin by the mouth. It was the destruction of the hormone by the trypsin secreted by the gland that stood in the way of the earlier experimenters, and it is now known that insulin is also destroyed by pepsin. The chemical constitution of insulin is, however, not yet known. The fact that it is destroyed by pepsin and trypsin seems to make it probable that it is in the nature of an albumose, but Professor Macleod suggests as a possibility that it is really only adherent to this protein and itself has a much simpler chemical structure. Another question asked by Sir Thomas Horder was whether there was any hope of recovery of the pancreas in diabetics. While admitting that nothing definite can yet be said on the point whether continued treatment with insulin will enable the diabetic patient to recover any of his lost power of producing internal secretion in his own pancreas, Professor Macleod mentioned the observation that islet tissue develops considerable powers of regeneration after much of it has been destroyed as a result of ligation of the secreting ducts of the gland. In the course of the discussion at Portsmouth Dr. E. P. Poulton made rather encouraging statement, as he had observed some increased toleration in three out of four mice.

As to the exact value of insulin in the everyday treatment of diabetes, it is yet too soon to speak. There is a general consensus of opinion that it produces an immediate and dramatic effect in diabetic coma, and that the patient's symptoms may afterwards be held in control by suitable dieting. As to whether it is necessary to use insulin in mild cases opinion is yet very far from being settled. Professor Macleod probably expressed the present position well when he said that as an adjunct to therapeutic control treatment with insulin greatly improves the nutritive condition and increases the resistance towards infection, a complication to which diabetic patients are particularly prone.

action of drugs—muscle, blood, central nervous system, sense organs, heart, respiratory canal, alimentary canal, and kidneys. Professor CHARLES RICHET, President of the Congress when it met in Paris three years ago, was a worthy successor and disciple

## SEGREGATION OR AGGREGATION?

THE Ministry of Health has issued a very useful report<sup>1</sup> by Dr. J. R. Hutchinson in which the important question of the influence of hospital overcrowding on the occurrence of return cases and the spread of cross infection is discussed. The report also raises incidentally the question of the relation between scarlet fever and diphtheria. It appears that the Abingdon Isolation Hospital was well planned, and had, on the Ministry's standard, accommodation for 46 patients, which was ample for the needs of the borough and rural district. From time to time, however, agreements were entered into for taking patients from other districts, and on visiting the hospital Dr. Hutchinson found 124 beds and 120 patients. This overcrowding had existed for a considerable period, and at one time there were as many as 138 patients. The total population attempted to be served was 110,000. One of the areas is the Ramsbury rural district, and here it appears that as a matter of routine all cases of scarlet fever and diphtheria are removed to hospital at the instance of the notifying practitioner. Through admission and discharge of patients the Ramsbury district and the hospital were thus in frequent association, and the position of Ramsbury village as to disease prevalence is notable. For several years prior to 1922 the district had been almost completely free from scarlet fever and diphtheria, but in that year there were 91 cases, of which 79 were in the village; there were 57 cases of scarlet fever, and 19 of diphtheria; in 3 cases both infections were present simultaneously. In 17 houses a total of 60 cases occurred, 46 of them in 10 houses. The length of time over which the cases were spread and the change of infection in a house from scarlet fever to diphtheria pointed to reintroduction from without. This view is strongly supported by a detailed analysis of various groups of cases. In the Abingdon borough and rural district the practice was similar, and there was similarity in the effects. On the other hand, in the West Berkshire combined districts, comprising 70 per cent. of the total population served by the hospital, only a minimum of cases were sent to it, home treatment being adopted wherever practicable. The case rates per 1,000 of population in the three areas are significant. For scarlet fever Ramsbury rural district had a rate of 9.7, Abingdon borough and rural district 18.5, and West Berkshire only 3.0. For diphtheria the corresponding rates per 1,000 population were 1.7, 2.1, and 1.0. It is impossible to disagree with Sir George Newman's prefatory note, in which he says it would be far better in many cases to treat the patients at home than to submit them to risks of cross infection and damaging sequelae. In short, we may summarize the lesson of the report by the title of this note. If a hospital is overcrowded, its patients are not segregated but aggregated, and even though the cubic space per case may still be greater in the hospital than at the child's own home, yet in the former the risks of cross infection may much more than counterbalance the advantages of the extra cubic space. This should always be borne in mind in the administration of a hospital for infectious disease, especially if it possesses no isolation block composed of multiple cubicles entirely separated from each other, for treatment of doubtful or mixed infections.

## THE UNIFICATION OF PHARMACOPOEIAL PREPARATIONS.

THIS year's meeting in London of the International Pharmaceutical Federation was arranged to coincide with the diamond jubilee session of the British Pharmaceutical Conference, held last week at Great Central Hotel, Marylebone. The Federation represents twenty countries, and

<sup>1</sup> Report by Dr. J. R. Hutchinson on the Incidence of Scarlet Fever and of Diphtheria in 1922 in the village of Ramsbury, etc. London: H.M. Stationery Office. 1923. Pp. 28. 9d. net.

delegates from France, Italy, Spain, Belgium, Holland, Roumania, Greece, Australia, South Africa, the United States, Czechoslovakia, and other nations were present. The president, Professor van Itallie, dean of the University of Leyden, devoted a large part of his inaugural address to the problem of an international pharmacopoeia, and pointed out that in these days of increased traffic between countries the absence of uniform standards in medicine is an anachronism. As president of the committee for the pharmacopoeia of Netherlands he realized the amount of work connected with its periodical revision, and advised that a central international bureau should be formed to do the work of revision for all pharmacopoeias. In this way we should arrive at uniformity at least in the case of the more important drugs and their preparations. Mr. J. J. Hofman (Holland) said that the Belgian Government, which had brought together the Brussels Conference of Potent Drugs of 1902—a conference which resulted in a valuable international agreement of 1906—had been asked to approach the other governments in order to convene another conference which should decide on the formation of an international pharmacopoeial bureau as outlined by Professor van Itallie. No answer had as yet been obtained from the Belgian Government, and if unfavourable another Government could be found to take the matter in hand. Mr. Y. Cofman (Roumania), in a communication dealing with the same subject (the international uniformity of medicinal preparations), suggested a different way of attacking the problem. He presented to the conference, in collaboration with other members, a number of monographs on several important drugs—for example, those on opium by H. B. Stevens, on cinchona by C. T. Bennett, and on belladonna by A. J. Jones. Each of these monographs dealt with its subject in an exhaustive manner, giving comparative tables of the formulae and strengths in all existing pharmacopoeias, and a reasoned criticism of the various methods in use. It was suggested that this preliminary work of documentation should be continued in the faculties of medicine and pharmacy of every country, and, when all the information necessary for unification had been obtained, a conference of medical men, pharmacists, and analysts should meet under the auspices of the Health Department of the League of Nations and decide which formulae and methods could be universally adopted. The proposal will be considered by the permanent bureau of the Federation. Several other matters of interest were discussed. Dr. C. Rousseau (France) presented a thorough report on pharmacopoeial nomenclature, showing the dangerous confusion which exists at present, the same product being in certain cases known officially—in seventeen countries—under fourteen different names. The seriousness of the situation is indicated by the fact that the official name for calomel in Belgium is hydrargyrum praecip. alb., and that the tinct. camph. co. of the Portuguese pharmacopoeia is a liniment containing twenty times as much opium as its British synonym. Other reports dealt with patent medicines and with recent legislation on dangerous drugs which, though arrived at an international agreement through the intermediary of the League of Nations, still shows variations from one country to another. The clause which places the responsibility of dispensing a forged prescription on the shoulders of pharmacists was criticized, and various resolutions on matters of pharmaceutical interest were passed.

## BRITISH GUIANA MEDICAL SERVICE.

IN August, 1922, the Governor of British Guiana appointed a committee "to consider and report as to what best could be done to place the medical services of the colony on a satisfactory and permanent basis." The committee held its first meeting in August, 1922, and reported

one of the principal objects of the section. However, endorsed the chairman's view that such should be an English translation of *The Internal Secretions of the Sex Glands*, by Dr. A. Lipschütz, professor of physiology in the University of Dorpat, Estonia, will shortly be issued by Messrs. Hether and Sons, Cambridge. Dr. F. H. A. Marshall, F.R.S., of Christ's College, Cambridge, has written a very ordinary, but not uninteresting, review of the *Internal Secretions of the Sex Glands*, a special course will be given from September 17th to 25th. Copies of the programme and further particulars can be obtained on application to the Secretary of the Australian Congress, 18, Beaulieu Square, London, S.W.1.

The travelling scholarship of the People's League of Health has been awarded to Miss Alice Gwyn, who has been in charge of the Cambridge Day Sanatorium since 1917. She will attend Dr. Koelliker's course on histology at Leyden.

The well attended Dr. Koelliker's course on histology at Leyden, and will also visit the Granacher and other institutions in France for the treatment of tuberculosis in Switzerland.

As a memorial to the late Dr. Philip Hicks (a brother of Sir William Douglas Hicks), senior medical officer of the Royal London and Counties Home for Incurables, Leamington, a handsome shelter was dedicated and opened at the home on July 15th, by Sir Ernest Pollock. The shelter was erected by subscription from friends and patients of Dr. Hicks, and bears a memorial tablet.

From June 4th to 10th 54 cases of plague occurred in Egypt, including 3 in Alexandria, 2 in Port Said, and 1 in Suaz.

The fifth Cambridge International Post-Graduate Course, in which special attention will be given to medical hydrology and balneotherapy, will be held at Carlsbad from September 15th to 18th. Further information can be obtained from Dr. Edgar Ganz, Carlsbad.

We regret to have to record the death of Dr. W. Ford Robertson, pathologist to the Scottish Lying-in Hospital. We hope to publish some account of his career in a later issue.

## QUESTIONS AND ANSWERS.

---

TRAINING OF A PARALYTIC.

Dr. R. E. PAYLER (Trowbridge, Wilts) is concerned about the case of a young man aged 21, partially paralysed by an accident when 10 years of age, but able to walk, though with some difficulty. There is some slight incoordination of the hands, which, however, is said to be improving. Our correspondents wish to hear of an institution where instruction in some such occupation as basket-making or book-binding could be obtained. His mother is able to pay a small premium or make some contribution towards the cost of education.

DOCTOR OR SMALL MATERNITY HOSPITAL.

Dr. E. S. ROBINSON (Stonport) asks for information as to the cost of establishing and (b) running a small maternity home—say of four beds—in a small country town.

important, in the interests of the patient as well as of others, that a diagnosis should be made as early as possible, and under the tuberculosis schemes of local authorities facilities are available for assistance in diagnosis, including the services of the tuberculosis officer for consultation. The object of the regulation is stated to be to make it possible to take steps to prevent the spread of infection, to discover other possible cases among those who have been in contact with the patient, and to ensure that the patient receives to the fullest possible extent the treatment best suited to his condition.

#### INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.

We announced recently (July 14th, p. 76) that the committee of British ophthalmologists formed to arrange for an international congress of ophthalmology to be held in London, 1925, had decided that it must be postponed on the ground that French and Belgian ophthalmological societies had passed resolutions to the effect that they felt themselves unable to participate in a congress if Germans were admitted. We have now received a letter from the General Secretary of the Société française d'Ophthalmologie stating that the French and Belgian societies fully agree that German, which is used for scientific communications by several nations, should be one of the official languages at the proposed congress in London, and that they are ready to co-operate with ophthalmologists in Austria-Hungary, Bulgaria, and Turkey; but they adhere to their decision not to take part in the congress if Germans are invited to attend. They consider that in taking this course they are acting in accord with the resolutions adopted at the conference arranged in London by the Royal Society in 1918. The resolutions then adopted were confirmed by the Conseil International de Recherches held in Paris in July, 1922. The reasons given on these two occasions still apply, in the opinion of our French and Belgian colleagues, to the attitude assumed by Germany and the German medical profession. From the wording of the communication we gather that French and Belgian ophthalmologists think that the question of holding an international ophthalmological congress in London in 1925 is still open, but we have not received any communication from British ophthalmologists since that published on July 14th.

#### ROCKEFELLER MEDICAL FELLOWSHIPS.

The Medical Research Council announces that it has awarded Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1923-1924, to John Crichton Bramwell, M.D.Cantab., M.R.C.P., Medical Registrar and Registrar to the Cardiographic Department, Manchester Royal Infirmary; Norman McOmish Dott, M.B., Ch.B.Edin., F.R.C.S.Ed., Assistant in the Physiological Department, University of Edinburgh; Helen Ingleby, M.B., B.S.Lond., M.R.C.P., Assistant Physician Victoria Hospital for Children and South London Hospital for Women; Hugh Kingsley Ward, M.B.Sydney, D.P.H.Oxon., member of the scientific staff of the Medical Research Council working in the Department of Pathology, University of Oxford. Further awards may be made during the coming academic year.

The Dinner in celebration of the hundredth year of the *Lancet* will be held at the Hotel Victoria, Northumberland Avenue, London, W.C., on Thursday, November 29th, 1923, and not, as previously announced, on November 28th. Mr. Neville Chamberlain, the Minister of Health, has signified his intention to be present.

#### ANNUAL MEETING NOTES.

##### THE ANNUAL REPRESENTATIVE MEETING.

THE chief business on Tuesday, July 24th, was the reception and approval of the report of the Dominions Committee and of that section of the Organization Report which dealt with Oversea Branches. The grouping of items from the two reports enhanced the effect, which, as usual, was a happy one, and owed much to the cordial expressions of good-will from the several oversea representatives present. Dr. Morton Mackenzie's introduction of the South African section of his report was particularly effective. He succeeded in conveying a very definite impression of the complex and difficult medical position in the Union, and at the same time vindicated the attitude taken by the Council throughout negotiations with the several parties into which the South African profession is unfortunately divided; Dr. Baumann's tribute to his efforts towards agreement was fully justified. For obvious reasons Dr. Baumann himself refrained from comment on the present position. The resolution expressing regret at the unsatisfactory conclusion of the negotiations with the Colonial Office in respect of the Windward Islands Medical Service, and endorsing the Council's action in inserting an Important Notice with regard to appointments in that service, as well as the other steps taken to bring existing conditions to the notice of prospective candidates, was well received. Unfortunately the representative nominated by the Grenada Branch arrived late, but his subsequent speech had the merit of drawing attention to the gravity of any decision which might cut off from a portion of the Empire, for any reason, the supply of British-qualified practitioners. The Representative Body had also to consider reports from the Irish and Scottish Committees, from the Committee on Notification of Venereal Diseases, and from the Non-Panel Committee. A point of interest arose on the report on notification of venereal diseases. No specific recommendation was made by the Committee, and there was danger on the one hand that the public might receive a false impression of the attitude of the profession to so urgent a matter if the report passed without discussion; on the other, that an ill advised resolution might hinder useful development along the lines of the Trevelthick report. The Chichester and Worthing motion, as finally amended after discussion, avoided both dangers. Dr. McGregor-Robertson scored a success by his contribution to the satisfactory solution obtained. The conclusion of the business of the meeting by 3 p.m. was an effective witness to its admirable conduct by the Chairman. Altogether the Representative Body may congratulate itself on the expedition with which it disposed of its long four days' agenda.

##### THE BISHOP OF WINCHESTER'S SERMON.

A religious service for the Association, which was largely attended by members, was held at Portsmouth Parish Church (St. Thomas à Becket) on Tuesday afternoon. The service was conducted by the Rev. W. H. David, and included special prayers for the sick, for the medical profession, for nurses, for students, and for medical missions. The sermon was preached by the Bishop of Winchester, who spoke from the words "With reverence and godly fear" (Hebrews xii, 28). He disclaimed any suggestion that he had chosen this subject of reverence because he thought the man of science an irreverent man, proud of his knowledge, and without the fear of God before his eyes. In his mental gallery some of the noblest types of reverence and faith were surgeons and physicians. But he thought that a few words on this subject might perhaps strike the keynote of the Annual Meeting, and send those present into their discussions with a refreshed sense of the value and dignity of

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 88. Chronic Urticaria and Angio-Neurotic Oedema.

H. W. BARBER (*Brit. Journ. Derm. and Syph.*, June, 1932, p. 203) considers that the majority of cases of chronic urticaria in adults, whether accompanied or not by angio-neurotic symptoms, are due to sensitization to bacterial

rather than to food proteins, and the same holds for asthma

the outward signs of sensitization in which there is secondary

susceptibility and hyperexcitability of the nervous system.

In bacterial sensitization the sensitivity generally develops

during an acute infection, subsidence of which leaves a local

focus in which the infecting organisms is still active and likely

to give rise to recurring symptoms of sensitization—for

example, urticaria or asthma—and such foci are important

for that reason, apart from the additional possibility of direct

bacterial invasion of the blood stream taking place from them.

While the necessity for surgical interference is obvious in the

case of abscesses of the teeth, chronic appendicitis, and nasal

sinus suppuration, mere enlargement of the tonsils is no indica-

tion for their removal, this being necessary only when they are

septic, the main indication being infection of the anterior

palatal folds and tonsillar tissue, the presence of septic

material, and partial engorgement of the lymphatic glands.

Anything short of complete emuculation of the tonsils is

neglects, previous incision operations being responsible for

the development of violent infections. The *Streptococcus*

*longus* appears to be the organism most commonly responsible,

but an artificial eruption may also depend on sensitization

to the *Bacillus coli*, or *Staphylococcus aureus*, or other

bacteria, and many of the patients give a previous history of

the rheumatic fever. Notes and comments of six urticarial

cases are given illustrating the various sources of infection

responsible for the condition.

89. Treatment of Migraine with Peptone.

J. L. MILLER and B. O. KAVLSTON (*Journ. Amer. Med. Assoc.*, June 30th, 1932, p. 1894) report the results obtained in twenty-

five cases of migraine from the injection of a 5 per cent.

solution of peptone. The solution is prepared by dissolving

the peptone in 0.9 per cent. sodium chloride solution so as to

make a solution of about 6 or 7 per cent. strength, and this is

neutralized. The solution is then made up to the volume

required to make a 5 per cent. solution, filtered until clear,

and then placed in 5 c.cm. ampoules and autoclaved in the

usual manner. In order to determine whether the prepara-

tion is sterile, the ampoules are incubated, and if they

remain clear they are ready to use. The first intravenous

injection is 0.5 c.cm., the dose being rapidly increased to

2 c.cm. The interval between injections is relatively unin-

terrupted. Miller and Kavlston have usually given two injec-

tions a week until the headache disappears; then weekly,

and, if the improvement continues, once in two weeks, and

finally once a month. It has not been determined how

frequently the injections must be given in order to prevent

a recurrence. This period will probably show individual

variation. If the injections are discontinued, sooner or later

the migraine will return. The longest period of freedom

observed after discontinuance of the treatment was nine

months. The total number of injections given varied from

six to forty-two. Expressed in

per cent., were not benefited. These results correspond

quite closely to those reported in the treatment of hay fever

by desensitization.

### 90. Diagnosis of Lead Poisoning.

A. ELLI and R. H. HEM DE BALSAC (*Paris med.*, May 26th, 1932,

p. 463), after examination of 179 workmen employed in

factories where lead was used, came to the following con-

clusions with regard to the value of the various clinical

signs in the early diagnosis of plumbism: (1) Some signs

are of real value, such as the blue line on the gums,

which is the most frequent and earliest manifestation.

It was present in 65 per cent. of 95 workmen engaged

in an accumulator factory, and was also found in 65 per

cent. of 85 carriage painters. In 25 per cent. the blue

line was very distinct, and in 40 per cent. faint. Most of

the workmen with the blue line showed red cells with

basophil granulations, but in about one-tenth of the cases

only one of these two signs was present at a time. In 5 to

6 per cent. of the cases lead colic was an initial sign, being

## 91. The Value of Drugs of the Morphine Group in Relieving Cough.

P. HECHT (*Klinische Wochenschrift*, June 14th, 1932, p. 1069)

records the results of clinical observations which he has

made in order to determine the value of various derivatives

of the morphine group in relieving cough. Codeine is more

satisfactory than morphine for the relief of cough, since it is

not generally narcotic. In its action and does not lead to the

formation of a drug habit. It is the most useful of all drugs

for the relief of cough and does not produce bad after-effect.

Severe paroxysms of coughing are often arrested by a small

cleanly large dose of codeine (0.65 gram), and the drug can be

discontinued without difficulty. The author has tried to find

a more powerful and cheaper substitute for codeine. He

describes the precautions necessary in testing clinically the

value of drugs for relieving cough, and the class of cases most

suitable for observation. Paracodeine and diion were found

to be less effective than paracodeine and diion. But from his observations

the author considers that "diion" is at least as effective as

codeine and is more effective than paracodeine and diion.

It is preferred by the patients and produces a definite feeling

of well-being; but in time a drug habit is formed and there

is difficulty in getting the patient to return to the use of

codeine.

92. Dangers of Intravenous Injections of Oil of Camphor.

J. FARNHOLM-JÖLLEBER (*Läkarskrift för Lager*, May 1st, 1932,

p. 333) considers the intravenous injection of oil of camphor

for collapse and acute pulmonary disease, such as pneumonia,

to be very dangerous. It has been argued that, provided the

injections are given slowly and not more than 5 c.cm. are

given at a time, little or no risk is entailed. In support of

these claims both clinical observations and experiments on

healthy experimental animals, and comparatively healthy

human beings, are not fairly comparable with morbid

patients in this connection. The author recorded two cases, in

both of which oil of camphor was given by intravenous in-

jection. In both cases the patient's state was alarming, and

in one of them, at any rate, death was probably inevitable.

But it was significant that the microscopic examination of

the lungs after Sudan staining showed in both cases extensive

fat embolism. In the first case only 1 c.cm. of oil of camphor

had been given by intravenous injection; in the second case

5 c.cm. had been thus given. The author suggests that the

physician who has set his heart on giving camphor by intra-

venous injection should use some other vehicle than oil.

93. Haemorrhage following Treatment by Bismuth Salts.

MARJON (Anal. de Acad. Med. chir. Esp., May 7th, 1932,

p. 379, in Arch. de med. chir. esp., May 19th, 1932, at

meeting of the Spanish Medical-Chirurgical Academy reported

four cases of severe haemorrhage, three of which were fatal,

in patients who had been treated for syphilis with bismuth

salts. Two of the patients showed a predisposition for

haemorrhage; one was a boy, aged 14, who had recently had

an attack of purpura haemorrhagica, and the other was a

man, aged 50, with arterio-sclerosis. Marjón does not think

that the bismuth salts were responsible for producing the

haemorrhages, but suggests that in persons with a pre-

disposition to haemorrhage special care should be taken in

their use. In the subsequent discussion J. Corvia and

Belarion, who had both had considerable experience in the

treatment of syphilis by bismuth salts, stated that they had

never observed any haemorrhages due to this cause, even in

persons liable to develop them, such as arterio-sclerotic

subjects.

174 A

Sutherland, Dr. Asher's paper was really the most striking contribution to the discussion, for it showed that, in country which even headquarters would be inclined to accept as a sufficient obstacle to corporate activity, the Division is able to exist as a distinct entity, and to bring the local profession into direct contact with the life of the community. Dr. Livingston's paper dealt with an area which might have been thought difficult had not the Caithness and Sutherland comparison been supplied in advance. His suggestion that, whilst a close study of individual members and non-members with constant personal contact is the first essential of successful organization, it is a good policy for the secretary himself to direct rather than carry out the policy adopted in connexion with propaganda, was on a high plane of statesmanship—but it requires a statesman to give it full effect. It was unfortunate that Dr. Farquhar Murray should have been prevented from attending. In his paper he laid particular stress on the necessity and possibility of offering to the newly qualified such a welcome as will ensure their membership at the outset of their professional career, and indicated his methods of providing them with material help as well as general good fellowship. Mr. Webber gave a clear and stimulating sketch of the manner in which Nottingham is meeting the definite, though admittedly limited, demand for facilities for local post-graduate work in the Divisions and Branches. The discussion that followed showed the wisdom exercised in the selection of the openers and the preparation of the papers, for the difficulties dealt with, and the questions raised, were those common to the majority of areas, while the practical suggestions made were clearly applicable to many cases. There was general agreement on the importance of social activities, as providing the basis of personal fellowship essential to sound medico-political work; on the importance of the most critical scrutiny and analysis of members' and non-members' lists, and the importance of attracting the newly joined. The moral of the whole discussion, implicit if clearly stated in all that was said, was that it is an absolute essential of success in local organization for those responsible for the direction of Association activities to have a definite scheme, based on the particular needs of their areas, and to work to that scheme deliberately and persistently. It was unfortunate that an excellent suggestion for raising the status of the Conference and securing its continuity, by electing the chairman for the next meeting, was not formally proposed, and lapsed, presumably through an oversight. The discussion after tea was ragged. "Consideration of the member and non-member percentages" was too indefinite an item to secure any constructive suggestions, more especially as those present had not had an opportunity of considering the document beforehand. It was, however, the occasion of an extremely useful and interesting statement by Dr. Drever of the manner in which he has analysed and classified the member and non-member lists for Scotland.

#### MEDICAL MISSIONARY BREAKFAST.

THE Medical Prayer Union held on July 25th what is hoped to be the first of a series of medical missionary breakfasts in connexion with the Annual Meeting of the British Medical Association. A large number of guests were present at the Queen's Hotel, Southsea, where they were welcomed by the President, Mrs. Scharlieb, who was supported by the Bishop of Winchester, Bishop Ingham, the President of the Association (Mr. C. P. Childe), and the Medical Secretary (Dr. Cox). Greetings from the Association of Medical Missionaries in China were conveyed by Dr. Duncan Whyte, who emphasized the satisfaction of medical work abroad, and ascribed it to the absence of any fear of competition, the ability to treat poor patients

freely, and the opportunity of taking up any specialty with certainty of abundant material for investigation. The meeting was addressed by Dr. G. E. Dodson of South-Eastern Central Persia, and Dr. C. C. Chesterman of the Congo. Dr. Dodson drew a vivid picture of the Persian plateau, with its extremes of climate, and its intelligent Aryan population, debarred by the influence of the Koran from progress along Western lines. He contrasted the conditions of public health twenty years ago with those brought about by the patient labours of medical missionaries, and spoke particularly of the ravages of rickets, due to the custom of putting little children, at the age of 5 or 6, to work at the carpet looms. They sit on planks in sunless, airless hovels from sunrise to sunset, with half a day's holiday in the week, and their pay allows only of a diet of dry bread and dried skimmed milk. Many hundreds of cripples had been relieved by transverse osteotomies, but for the girl wives the pelvic deformity means certain death at the first pregnancy. Dr. Clement Chesterman approached his subject from the psychological aspect, and suggested that the mentality of the African native might be compared with that of the paranoiac in its suspicions and terrors of persecution. The difference between the native and the civilized mind and physique he ascribed rather to an endocrine problem than to a different stage of evolution, and believed the psychological condition to result from an inhibition of love. He described the medical work in Africa as a process of combating great scourges that sweep the country rather than treating "cases" of disease, and spoke of the successful results now being obtained with trypanamide injections for sleeping sickness. A brief speech by the Rev. Dr. J. G. James, and benediction pronounced by the Bishop of Winchester, closed a very successful meeting.

#### THE TEMPERANCE BREAKFAST.

A PUBLIC breakfast was held at the Town Hall on Thursday morning, by invitation of the National Temperance League. The President of the British Medical Association (Mr. C. P. Childe) took the chair, and the hostess was Dame Sophia Wintz, successor to the late Dame Agnes Weston in the work of the Royal Sailors' Rests. The principal address was given by Mr. C. J. Bond of Leicester, who repeated some of the statements made in his presidential address to the Society for the Study of Inebriety (BRITISH MEDICAL JOURNAL, July 22nd, 1922, p. 142) on the expenditure on alcohol of certain large voluntary hospitals over a period of more than a century. He showed that the expenditure rose and fell very much in accordance with national expenditure under the same head, and that the hospitals, in respect to alcohol consumption, had not led public opinion but had followed it. The records also showed the result of the influence of individual teachers at the medical schools who happened to have strong views, one way or the other, on the subject of alcohol. He had something further to say about the salvage work which these institutions performed. To an unrealized extent the voluntary hospitals of this country, at great cost to themselves, were rescuing people from the results of their own anti-social indulgence. The present was a very important time in temperance progress, and it was very necessary that the members of the medical profession should inform themselves of the latest results of scientific inquiry with regard to alcohol. Sir Robert Armstrong-Jones proposed a vote of thanks to Dame Wintz and the President; this was seconded in an amusing speech by Sir StClair Thomson, who spoke of the pleasure with which he found himself side by side with his fellow-student, the President. Even in those days Mr. Childe had a calm and judicious mind, that right judgment in all things for which we prayed every Sunday, and he was also a good sportsman.

in blood sugar occurred. There was a slight fall during the first twenty minutes, and then either no decline or a very gradual decline for hours. The glucose injected did not automatically leave the blood stream, but fell only when an active pancreas was present, presumably due to the excretion of insulin. This was also suggested by the drop in the normal curve to a subnormal level. Insulin in an active form disappeared rapidly from the blood after pancreatectomy. In blood taken from dogs after large doses of glucose insulin had not been demonstrated. The response to glucose injection was essentially the same, though slightly delayed in a dog with a large denervated pancreatic graft.

Dr. J. R. MURLIN (Rochester, New York) read a joint paper by himself, Mattill, Piper, and Kimball on the chemical and physical properties of insulin. It was stated that a rapid method of preparing insulin had been worked out based upon the following properties: thermo-stability to boiling point as shown by Murlin and Kramer, 1913-16, solubility in water, precipitation by complete saturation with sodium chloride, solubility in 70 per cent. ethyl alcohol, and precipitation by means of amyl or butyl alcohol.

Fresh pancreas, of beef preferably, was macerated in 4 volumes of 0.2 N HCl and brought rapidly to the boiling point. After cooling it was neutralized to a pH of 4 and filtered overnight. The first filtrate, when given by the stomach to dogs made diabetic by the removal of the pancreas, controlled the diabetic symptoms. It therefore resisted peptic digestion. Precipitation of extraneous proteins with sodium chloride seemed to offer some advantages over ammonium sulphate, as suggested by Shaffer. The entire precipitate was soluble in 70 per cent. ethyl alcohol, from which the potency might be precipitated by 3 to 5 volumes of amyl or butyl alcohol. The final precipitate was readily separated by centrifuging, and, after the amyl alcohol had been removed by vacuum distillation, it was then dissolved in sterile water to make an extract of any desired concentration. In final form it gave a very faint biuret reaction which appeared to be due to traces of protein as impurity. Each step must be carried out at a definite hydrogen ion concentration. For thermo-stability the reaction might be at a pH of 6.7 to 7.2, or below a pH of 4. Between these limits the potency seemed to be regularly destroyed by heating to 80° C. for half an hour. For stability in final form the reaction might be from a pH of 4 to a pH of 2. Preparations had been kept for four months without loss of potency.

Potency did not seem to depend upon nitrogen content, and its thermo-stability and survival in acid reaction up to 0.5 N HCl indicated that insulin could not be an enzyme, but was properly called a hormone.

In a paper on the part played by insulin in carbohydrate metabolism Dr. GUNNAR AULGREN (Lund) said that respiration in tissues from normal and from depancreatized animals had been studied both with and without the addition of insulin. The power of the tissue to reduce methylene blue (Thunberg's method) had been used as a measure of the tissue respiration. When glucose and insulin were present in suitable concentrations the glucose was split into products able to serve as substrate for the oxidizing enzymes, as was indicated by the accelerated decolorization of methylene blue. Fructose and galactose were split by the tissues without the aid of insulin. Insulin did not accelerate the oxidation of  $\beta$ -oxybutyric acid, lactic acid, and glycerophosphoric acid.

#### Functional Activity of the Suprarenals.

Dr. W. CRAMER (London) described some experiments demonstrating the functional activity of the suprarenals. By the histo-chemical method the granules of adrenaline could be rendered visible both within the cells of the medulla and in the process of secretion into the blood. In this way direct and conclusive evidence could be obtained concerning the conditions under which secretion of adrenaline occurred. The method had the further advantage that the animal could be kept under perfectly normal conditions, so that the factors determining secretion were studied without the interference of anaesthetics or surgical procedures which of themselves excited the secretion of adrenaline. In this way experiments on mice had demonstrated a very distinct secretion of adrenaline under a number of conditions. The observations showed: (1) That in response to specific stimuli the adrenal medulla was capable of an autonomous vigorous secretion as definite as the secretion of the pancreas or

salivary glands. (2) That one of the most important functions of the gland which it exercised through the secretion of adrenaline was a metabolic one connected with the heat regulation of the body. Both the physical and the chemical heat regulation of the body were under the influence of the sympathetic system. Thus general sympathetic stimulation produced mobilization of the liver glycogen; the body cells responded by increased oxidation to this inflow of carbohydrate into the blood stream under the influence of sympathetic stimulation. Increased heat production resulted. The physical heat regulation depended on the calibre of the cutaneous vessels, and in some species of animals on the activity of the sweat glands, in others on the erection of the hairs of the fur. These three factors were also under the influence of the sympathetic. Thus hyperactivity of the adrenal medulla with massive secretion of adrenaline produced a fever due to increased heat production and diminished heat loss—"sympathetic fever." Conversely, adrenal insufficiency due to exhaustion of the gland or to other causes led to a subnormal body temperature. The thyroid gland had a synergetic action. The action of the thyroid hormone was slower and more prolonged than that of adrenaline. Its direct action on metabolism and on the heat regulation of the body was effected mainly by continued mobilization of the liver glycogen. Climatic conditions produced their effect on metabolism and on the nervous system generally in virtue of the fact that increasing the loss of heat from the body acted as a powerful stimulus to the functional activity of the adrenal and thyroid glands.

#### Internal Secretion of the Testicle.

Drs. E. RETTERER and S. VORONOFF (Paris) read a paper on the relation of physiological phenomena with the structure of the grafted testicles. Histological examinations practised every month for nearly two years by Professor Retterer upon testicles grafted by Dr. Serge Voronoff clearly proved that from the moment when the testicular cell is transformed at a certain age to a specific element, notwithstanding morphological changes produced by the graft, that cell continued to possess the property of elaborating products of internal secretion which determined the physiological phenomena.

#### The Thyroid and the Autonomic Nerves.

Dr. HENRY DRYERRE (Edinburgh) said that in an attempt to relate the different views as to the action of thyroid preparations upon the autonomic nerves, he had investigated such effects resulting from the injection of thyroid extracts and of thyroxin upon these nerves, as might be manifest in experiments lasting several hours. To allow for individual idiosyncrasies a large number of animals were used and inquiry was made also into modifications caused by the anaesthetics used. The experiments had been conducted at such intervals that any seasonal variations in the responses might be noted. The results were not consistent and similar results could be obtained by the injection of extracts of spleen, of liver, and even of simple Ringer's solution. It was also demonstrable that such variations in the responses could occur without any injections having been made. The conclusion was formed that injections of extracts of thyroid gland or of thyroxin had no specific action upon the sensitiveness of the cardiac fibres of the vagus, or on the depressor nerve, which could be demonstrated in the course of an "acute" experiment.

#### Antidromic Action.

Professor J. N. LANGLEY (Cambridge), in a paper on antidromic action, said that the brilliant flush normally produced in the pad and too cushion in decerebrated cats by stimulating the peripheral ends of the posterior roots of the seventh lumbar nerve ceased on section of the superficial plantar nerves a little proximally of the pad, and there were only slight and variable effects. From a consideration of this result and of the results of varied observations on stimulation after nerve section he concluded that antidromic impulses did not cause appreciable dilatation of arterial trunks in any part of their course down to the digital arteries.

If the abdominal aorta were clamped, stimulation of the

### THE MANCHESTER AND DISTRICT RADIUM INSTITUTE.

THE annual report of the Manchester and District Radium Institute for the year 1922 relates the result of the first complete year's work of the Institute in its new building. The number of cases registered for treatment was 799, a slight increase over the number for the previous year; 514 emanation plates and 1,281 emanation tubes were made during the year, which represented practically the full capacity of the emanation plant. The total number of malignant cases treated was 584, and of these 59 were rendered free from sign and symptoms of disease during the year. Thus the percentage of perfect immediate results following radium treatment was slightly over 10. The best results were still obtained with carcinoma of the cervix uteri; 29 cases were apparently cured. With improvement in the technique in the treatment of carcinoma of the mouth and tongue with unscreened emanation tubes the number of successful cases showed a gratifying increase to 10. The number of cases of rodent ulcer that came up for treatment was 85, and 41 were apparently cured.

The total number of out-patient attendances during the year was 4,900; the in-patient attendances numbered 912. The increased number of in-patients was made possible by the accommodation now provided at the new Radium Hospital. During the year considerable improvements have been made in respect of the protection of the workers at the Institute. A lead box with walls one inch thick for the holding of emanation tubes has been constructed and so arranged that the door opens downwards, and thus gives considerable protection. A second device has been adopted with the object of protecting the nurses' fingers when making up plates for application of radium from the surface, whilst the emanation plant has been completely covered by adequate lead protection. Investigations are in progress for the treatment of cases of inoperable carcinoma by means of a combination of radium and diathermy, and a diathermy apparatus has been installed at the Institute for this purpose. At the same time the application of deep x-ray therapy combined with radium is being carried out with the aid of the two new intensive x-ray outfits at the Royal Infirmary. It is too early yet to speak of the late results of this form of treatment, but the initial response is said to be satisfactory. Reference has already been made in a previous issue of the JOURNAL (June 2nd, 1923, p. 949) to the special research which has been conducted into the effects of radium on blood serum in health and disease, further work on which subject has still to be done. The report shows that the work of the Radium Institute is being actively carried on, and that the results of the treatment in a number of cases is encouraging.

### NURSES' HOME AT THE LIVERPOOL ROYAL INFIRMARY.

On July 24th the Duke of York laid the corner stone of the new Nurses' Home of the Royal Infirmary, Liverpool. Addresses of welcome to the Duke (who was accompanied by the Duchess) were read by the Lord Mayor of the City, and the President, Mr. Thomas H. Bickerton, consulting ophthalmic surgeon of the Royal Infirmary, who reviewed the history of nursing in relation to the sick. The name of William Rathbone will be for ever associated with the institution of a trained nursing staff for the sick poor of Liverpool. The present building, erected 63 years ago, has been enlarged from time to time as the demands of the Royal Infirmary increased, by the addition of houses in the immediate vicinity. The new building would have been begun long ago but for the war. The original estimate was between £40,000 and £50,000, but costs have increased so much that the money suffices only for the erection of one-third of what is necessary. Between £4,000 and £5,000 is required to complete and furnish this portion; with this object the Duchess of York had consented to receive purses, each containing £25. In this manner £2,085 15s. 6d. was presented. In his reply the Duke of

York expressed his pleasure at being present to promote so good a cause and made mention of his own personal indebtedness to the trained nurse's services. He presented a bronze medallion awarded by the Carnegie Hero Trust Fund to Mr. Charles B. Wood, who had been x-ray operator in the Royal Infirmary since 1903 and had become a victim of x-ray dermatitis necessitating several operations and now totally incapacitating him from performing his duties. A new gynaecological operating theatre was formally opened by the Duke, and finally the corner stone was laid. The consulting honorary staff and the senior members of the acting staff were presented to the Duke of York. An unfortunate event, due to the plunging of two startled carriage horses into the crowd just as the Duke was about to enter the Royal Infirmary, resulted in the injury (fortunately not serious) of some fourteen persons. They were immediately taken into the Infirmary and received the attention of Mr. Frank Jeans, one of the honorary surgeons. The Duke visited the sufferers before leaving the hospital.

## Scotland.

### SCOTTISH NATIONAL LIBRARY.

THE generosity of the Faculty of Advocates in Edinburgh and the munificence of a private donor, Mr. Alexander Grant, have combined to provide Scotland with a valuable National Library. Some months ago the extensive library in charge of the Faculty of Advocates was offered to the Government, so that it might be managed on national lines in Scotland, similar to those of the British Museum in London. An obstacle in the way of the acceptance of this offer was the absence of any fund to provide accommodation for the books. Within the past three weeks this difficulty has been removed by an Edinburgh citizen, Mr. Alexander Grant, who has provided £100,000 necessary for the permanent endowment of the library. This library has had an interesting history. It was founded in 1680, and the first catalogue, printed in 1692, contained no fewer than 3,140 entries. It was then valued at £14,400 Scots or £1,200 sterling, and included not only legal volumes but books in all departments of learning. In 1709 the Copyright Act of Queen Anne conferred on the library the right to claim a copy of every book entered at Stationers' Hall. This privilege has been confirmed in all subsequent copyright Acts, and applies to every book published in the United Kingdom. The library also has received from time to time numerous presents of books and manuscripts. Many of the latter especially are of great interest and importance. The number of volumes in the library is now well over 700,000. Among the most recent acquisitions is the letter written by Mary Queen of Scots to her brother on the morning of her execution. It is a beautiful specimen of sixteenth-century handwriting as well as a document of the first historical importance; it describes how, after having passed nearly twenty years in the captivity of Queen Elizabeth, the writer is ordered to be executed as a criminal. There are also in the library some twenty-one ancient Gaelic medical MSS. Of these sixteen are entirely medical and five or six partly medical. For their preservation we are indebted in the first place to two Celtic families who practised medicine in the Highlands of Scotland for several centuries. These were the family of McBeath or Beaton and that of McConacher of Lorn. The substance of these MSS. is taken largely from the ancient Greek and Arabic writers, and this fact shows a high standard of learning among the native Highland population of the Middle Ages. One of the MSS. is a treatise on materia medica, of which several copies are to be found in the British Museum and other places. Acknowledgements are made in it to the researches of the doctors in Salerno and Montpellier, but it is largely of native Scottish origin. It is to be hoped that, now that the MSS. are more accessible, some scholar may be found with sufficient knowledge of medicine, botany, and Gaelic to undertake the publication, especially of the last mentioned work.

# SOME APPLICATIONS OF PHYSIOLOGY TO MEDICINE. II.—VENTRICULAR FIBRILLATION AND SUDDEN DEATH.

J. A. McWILLIAM, M.D., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

(From the Physiological Laboratory.)

It may be permissible to recall that in the pages of this *downward* thirty-four years ago I brought forward a new view as to the causation of sudden death by a previously unrecognized form of failure of the heart's action in man—a view fundamentally different from those entertained up to that time. In the course of a long series of experiments on the mammalian heart, sudden deaths, occurring under varied experimental conditions, were found to be invariably associated with a very definite mechanism of failure entirely different in character from what had hitherto been believed to be present in cases of sudden dissolution in man depending on cardiac failure. Little attention was given to the new view for many years. At that time the current conception of the relations of the experimental physiology of the heart to practical medicine was widely removed from what it now is, thanks very largely to the work of Sir James Mackenzie and his associates and followers; it was not then recognized that most of the disturbances that have been experimentally induced in the mammalian heart (for example, fibrillation, flutter, heart-block, extra-systoles of various types, rhythms of abnormal origin, alternation of the heart beat, etc.) have their clinical counterparts in the manifold derangements of function in diseased conditions in man.

In more recent times the view that ventricular fibrillation is a cause of sudden death in man has been accepted by numerous observers. Sir James Mackenzie writes of sudden death in auricular fibrillation: "It has appeared to me probable that in these cases the ventricle has passed into fibrillation as MacWilliam suggested." Again, referring to sudden death from heart failure: "The cause of sudden death is almost certainly due to the onset of an abnormal rhythm, probably ventricular fibrillation." Sir Thomas Lewis states that "We have now the strongest *a priori* reasons for believing that sudden and unexpected death comes to many patients in a manner suggested by MacWilliam in 1889." The causation of death in this way has also been recognized by Hering<sup>1</sup> and many other observers.

Direct electrocardiographic curves indicative of ventricular fibrillation at the moment of death have been recorded, notably by an American observer, Halsey.<sup>2</sup> Opportunities for the gaining of such direct evidence are naturally scanty, but the indirect evidence that has accumulated is sufficient to show that this is, in all probability, not only a common cause but the usual cause of sudden and unexpected death of cardiac origin.

## Relation of Death from Fibrillation to Ordinary Myocardial Failure.

The mode of death described in this article is a failure of the heart's action essentially different from cardiac (or myocardial) failure in the sense of exhaustion of the contractile power of the cardiac muscle; a verdict in the latter sense would usually be, in cases of sudden death, fallacious. While such exhaustion of contractility is, of course, of common occurrence in disease, it is a gradual process, leading to more and more marked impairment of the pumping power necessary to maintain a good circulation and to respond to the increased demands of muscular exertion, etc. There is no ground for the assumption that a sudden loss of power can occur—that is, that muscular fibres endowed with contractility adequate for a tolerably good blood pressure and blood flow should abruptly become embroiled or paralyzed, apart, of course, from the sudden

engulfed or paralyzed, apart, of course, from the sudden death of cardiac origin.

## Sudden Death and the Pathological Changes found Post Mortem.

It is well known that in many cases where death is believed to have resulted from cardiac failure the heart has been found to have returned to present structural characters apparently little if at all removed from the normal. An elaborate study of sudden death and the pathological conditions associated with it was made by Hering<sup>1</sup> and Benham.<sup>2</sup> In this book, extending to more than 500 pages, a great deal is to be found as to numerous and varied morbid conditions and structural changes in various organs, etc., in cases where death has occurred suddenly, while it is stated that in some cases no lesion is found. Elaborate details of dead-house anatomy are presented, but no explanation is given, or indeed attempted, as to how vital function has suddenly broken down, when up to that point in many cases, in spite of pathological conditions that have often been present, the individual has been able to go about his affairs with fair or good activity of body and mind. It is obvious that such generative changes, etc., as were found after death were up to the sudden catastrophe, quite compatible with the tolerable efficiency of the functions necessary for the maintenance of function as may have been present up to the final disaster.

Some Characters of Ventricular Fibrillation.

The inception of ventricular fibrillation is a sudden event, though very often preceded by more or less complex disturbances in the normal action. There is an abrupt replacement of the effective systole by a continuous turmoil of rapid small contractions, each of short duration, consisting over the intercommunicating muscular fasciculi, so that, in all the muscular fibres during the normal systole. The result is more oscillation or inco-ordinated quivering of the ventricular wall, with complete loss of the expansive power normally brought to bear on the contained blood by the strong and simultaneous state of mechanical tension present in all the muscular fibres during the normal systole. The effect on the circulation resembles that of absolute stoppage of the ventricular beat with complete cessation of its muscular activity, such as may be caused by the introduction of certain poisonous agents, etc. While fibrillation is of universal occurrence, under certain conditions, in all warm-blooded animals—both mammals and birds—its tendency to persist when once established varies greatly, being much greater in the higher mammalian types. In some animals among the lower mammalian (rat, rabbit, etc.), as well as in

of the proposed transference are numerous and obvious, but a strongly entrenched conservatism still stands in the way.

#### THE UNIVERSITY.

The many friends of the Dean of the Faculty of Medicine, Professor Sir Harry Allen, will regret to hear that he has been given extended leave of absence on account of ill health. He has, however, made such rapid progress that it is hoped he may be enabled to resume active duty at an earlier period than was originally anticipated. Dr. F. L. Apperly, a Victorian Rhodes Scholar, has been appointed acting professor of pathology, and the duties of Dean are being temporarily undertaken by Professor Berry.

Dr. J. H. Anderson, Senior Lecturer in Anatomy, has resigned his position and will proceed to England. He has performed his manifold duties with such singular ability and conspicuous success as to make it certain that his loss will be severely felt. Dr. L. E. Hurley has been appointed to the vacancy.

The Director of the Walter and Eliza Hall Clinical Research Laboratory, Dr. S. W. Patterson, having received an important research appointment in England, has resigned. He is to be succeeded by Dr. C. H. Kellaway. Until the arrival of the latter the duties are being temporarily discharged by Mr. H. R. Dew, F.R.C.S.

#### THE AUSTRALASIAN CONGRESS OF THE BRITISH MEDICAL ASSOCIATION.

The arrangements for the first Australasian Congress of the British Medical Association are in an advanced stage and give every indication of a successful meeting. Visitors from overseas will be particularly welcome. They should communicate with Dr. A. L. Kenny, 13, Collins Street, Melbourne. Trade exhibitors should communicate with Dr. B. L. Stanton, Children's Hospital, Pelham Street, Carlton, Melbourne.

### Correspondence.

#### THE PRESIDENT'S ADDRESS.

SIR,—One of the best editorials I have read for years in the *BRITISH MEDICAL JOURNAL* is that of to-day. In it you state: "The President would rather have healthy dwellings to prevent tuberculosis than sanatoriums in which to treat it." And you ask, "What, then, is to be the remedy? More houses, and better houses, of course. But how are they to be provided?"

The answer, in my opinion, is easy, and it is this: The purchase of agricultural land, for building purposes, at double its agricultural value. It is not so much a question of houses—it is a question of sites! Thousands in this country could build houses, but houses cannot be built upon air. And agricultural land is the one thing, for building purposes, that cannot be obtained at market value.

If a Land Act were passed so that the individual could buy a sixth of an acre for £20 or less, the housing question would, in my opinion, solve itself. Strips of land, half a mile deep, on either side of the King's highway, should be purchasable at double the agricultural value—that is, for £60 to £120 an acre. And then the individual should be allowed to purchase one-sixth, and only six houses should be allowed to the acre. If this were done the ideal of a sixth of an acre, a cottage, and a goat (as a non-tuberculous milk supply) would become a reality. The capital cost would be only £350 to £450, or a rental of 6s. to 9s. a week, and this rental could be reduced by the sale of vegetables or milk. The other assets would be evening occupation, sunlight, fresh air, and fresh milk and vegetables—in other words, health.

If these sites were purchasable, water could be supplied by road mains, and the trams run out and electric lighting provided. The main road would take the place of costly streets; the sewage would go back to its natural place—the soil, and 20 to 30 per cent. of town dwellers would return to the land. This would leave more air space and better habitations in the cities, and workers living by the roadside could reach their work by tram, especially if assisted

by starting work at a reasonable hour in the morning. Every thrifty citizen, in my opinion, should have the chance of such a site, and I believe the response would enlighten the pessimists.

The best cottage or house would probably be one of "Redruf" bricks, with hollow walls, castellated top, and flat roof. The flat roof has many advantages, and could become a home sanatorium for a tuberculous inmate in the summer months.—I am, etc.,

Newcastle-on-Tyne, July 28th.

T. M. ALLISON.

SIR,—Mr. Charles P. Childe's Presidential Address on Environment and Health at the recent Annual Meeting of the British Medical Association at Portsmouth, as reported in the *BRITISH MEDICAL JOURNAL* of July 28th, 1923, is, if I may say so, a survey of the greatest interest and value, but I am greatly disappointed to see in the section on tuberculosis the President's statement of the conditions of cure of this disease. Mr. Childe states that fresh air and sunlight are the essential conditions, not only essential but almost the sole conditions, and says that the cures at Alton are fresh air and sunlight. I venture to suggest that the feature of treatment at Alton is Sir Henry Gauvain's efficient system of splinting of various types, and that fresh air and sunlight are only adjuvants, though very valuable ones, but possibly preceded in value by abundance of wholesome food.

In other words, surely the basis of successful treatment of tuberculosis is rest. If the children with active tuberculous foci at Alton and elsewhere took full advantage of fresh air and sunlight and yet maintained the unrestricted use of the affected parts, then I think there would be few, if any, good results from treatment.

The same in pulmonary tuberculosis—the sufferer must rest if symptoms of systemic disturbance are to be relieved. Repeatedly I have heard of patients with active pulmonary tuberculosis being advised to seek "fresh air," and who have sought it with much exercise often in hilly country, with steady decline in health, when it was rest in bed for which their organisms were calling. For a long time in this sanatorium I have preached to my patients and others the value of rest in treatment, and have curtailed considerably in winter the free open-air conditions which cause such discomfort, discontent, and even harm in this country, and the results of treatment have not been impaired.

Fresh air is, of course, of importance in the treatment of tuberculosis, but, like graduated labour for pulmonary cases, it can be overdone. I submit that the essential conditions for the satisfactory treatment of tuberculosis in order of merit are rest, good and plentiful food, fresh air and sunlight.—I am, etc.,

CECIL G. R. GOODWIN.

Barrasford Sanatorium, Northumberland,  
July 29th.

SIR,—The President in his address alludes to cancer, tuberculosis, venereal disease, and alcoholism as scourges responsible for many deaths. We can protect ourselves against the last three—is there no means of protecting ourselves against cancer?

Without going into the pros and cons of the many theories of the cause of the disease, it seems to me that there is more evidence in favour of the organismal hypothesis than of any other. It is very probable that the organism is a protozoon similar to the *Coccidium oviforme* in the liver of rabbits, and that it is a parasite which spends part of its life cycle in another host, from which we become infected. It is possible, too, that the parasite is present in the blood of most individuals, and that it requires some previous susceptibility of the tissues to attract it and cause the epithelial cells of the part to cross the border-line and become malignant. For have we not a somewhat analogous condition in trypanosomiasis? Trypanosomes have been discovered in the blood of individuals not suffering from manifestations of the disease, and are not trypanosomes attracted to tissues irritated by the injection of turpentine, producing a fixation abscess?

I suggest, therefore, that we should endeavour to anticipate the onset of malignant disease by giving, after the

other towns, proves that there are other factors besides the presence or absence of infantile vaccination which determine the severity of small-pox. It is too soon yet to pronounce a final verdict as to the lessons of the Gloucester epidemic, but in the meantime I cannot think that Dr. Croley's suggestion is either fair or expedient.—I am, etc.,  
Leicester, July 26th. C. KILLICK MILLARD.

SIR,—There is much that is very disturbing about the present small-pox epidemic; it makes many of us look foolish who have been preaching for years to the public on the dangers of small-pox; and it appears to justify some of the contentions of the antivaccinators.

For thirty-five years as medical officer of health here I have been urging vaccination and prophesying regularly that when infection was introduced and a real epidemic started people would have an eye-opener and a terrible reminder of what small-pox means in unvaccinated children, instancing the last Gloucester epidemic with its 413 deaths. Now we have had an epidemic running up to about one thousand cases with practically no mortality, and the majority of these cases is said to have been among unvaccinated persons.

One of the chief arguments of the antivaccinators has long been that small-pox, like typhoid and typhus, has tended to become less severe by reason of ordinary sanitation. Another claim of our "anti" friends is that we beg the question by calling a case small-pox if a child is unvaccinated, and chicken-pox if vaccination marks are clear. In this connexion let me give one instance. A colleague in the public health service, being liable to be called on for an opinion, went to Gloucester and received full instruction about distribution of rash on face and limbs, umbilicated vesicles, initial malaise, lumbar pain, etc., and was finally told, "If you find vesicles on the palms of hands and soles of feet you may call it small-pox." Shortly after he was called in consultation to a case presenting all these features. He gave his opinion "small-pox." As there was still doubt, a medical referee from the Ministry of Health was summoned, and he pronounced it "chicken-pox." When I asked what the reason was for this decision, my friend replied, "Well, the chief thing was that the child had good vaccination scars!"

Undoubtedly much chicken-pox has been, and still is, about. Over six months ago, before the present epidemic in Gloucester, we had a sharp outbreak here, and in the case of some of the children I remarked at the time: "If small-pox were about this child would probably have been sent to the small-pox hospital," but they were unquestionably chicken-pox, with successive crops of vesicles in the same patient.

One recent report I noticed to the effect that out of some 300 cases in one hospital only about 30 had been vaccinated, and yet no fatal case had occurred. If small-pox has become so mild that even in unvaccinated children it does not cause any mortality, we shall surely have to revise all our opinions about the necessity for early vaccination; but does not the whole thing look as if this widespread epidemic had been chicken-pox from first to last?—I am, etc.,  
Bromsgrove, July 29th. H. CAMERON KIDD.

SIR,—In a note on the differential diagnosis of small-pox and chicken-pox, Dr. Brand (July 28th, page 160) mentions two signs which he considers are pathognomonic and are "invariably seen in varicella and never observed in variola." He refers to the early vesiculation and crusting of the papules, and the contemporaneous presence of papules, vesicles, and crusts. As an embarkation medical officer in a Mediterranean port, I saw cases of small-pox modified and atypical in which the differential diagnosis tables of the textbook seemed of little use, and also in which the two signs mentioned were not infallible. That an eruption is heterogeneous will not carry great weight, since it may be heterogeneous in small-pox. In cases of small-pox incompletely modified, cases in which the lesions differ considerably in size will differ equally in rapidity of evolution. For this reason want of uniformity among the lesions of some cases of modified small-pox is conspicuous. Ricketts and Byles (*The Diagnosis of Small-Pox*, page 51) state, in

discussing modified small-pox, that "papules arrested in development, vesicles, pustules and crusts may all lie together on the same square inch of surface."

The two signs mentioned by Dr. Brand are of the greatest importance, but they are not infallible. Whatever the characters of the skin lesion in small-pox, the distribution is characteristic.—I am, etc.,  
Birmingham, July 30th. E. BAYLIS ASH, M.B., M.R.C.P.

#### ACTIVE IMMUNIZATION IN TUBERCULOSIS.

SIR,—Those who advocate so strongly the use of Spahlinger's methods fail to realize the results obtainable by active immunization with antigens of the tubercle bacillus and of the accompanying infections, reactions being controlled by the exhibition of iodine. The results are remarkable. In my own hands I am accustomed to obtain arrest in over 90 per cent. Turban I, 60 to 75 per cent. Turban II; and 30 to 40 per cent. Turban III. I have several cases of acute pneumonic phthisis alive after four to ten years. I am quite prepared to demonstrate the methods in any suitable institution, under any observation, provided I can nominate my own man to carry out the treatment and keep the patients under treatment as long as I wish. No capital expenditure will be necessary to carry out this demonstration—merely the salaries of the executive doctor and the laboratory expenses for the manufacture of the material. The tubercle bacillus antigen I propose to use is my solution of the tubercle bacillus in benzoyl chloride, preferably made from the patient's own bacilli.—I am, etc.,  
W. M. CROFTON.

University College, Dublin, July 30th.

#### EARLIER NOTIFICATION OF TUBERCULOSIS.

SIR,—The opportunity of following the life history of the patient diagnosed as, or suspected of, tubercle for a number of years in a large industrial area like Leeds in sanatorium, dispensary, and domiciliary consultation work confirms the opinion that our present system of tuberculosis notification is totally inadequate in controlling tuberculosis.

So far notification has only served the purpose of providing a haphazard form of treatment in established disease causing systemic disturbance. Even with modern methods of treatment only in a very small number of cases has the expectation of the life of such consumptives been prolonged for a period of five to seven years in an industrial area. The press and the public clamour for treatment. The aim of notification should be to trace the beginning of the disease and to educate the patient to maintain his resistance, that his expectations of life may be as good as that of a normal individual, and thereby prevent the spread of the disease individually and socially. One has only to glance at the illuminating report of the Chief Medical Officer of the Ministry of Health for facts and figures that cry aloud for radical reforms in our system of notification and diagnosis of tuberculosis. The statistics for 1921 cannot but arouse us from our lethargy.

|                                                                                                 |       |
|-------------------------------------------------------------------------------------------------|-------|
| Tuberculosis of all forms—number of new cases notified to the Ministry                          | 71,70 |
| Tuberculosis of all forms—deaths registered in England and Wales (1921)                         | 42,6  |
| Of these, death from tuberculosis of the respiratory system (73 per 1,000 deaths of all causes) | 33,5  |
| Death from bronchitis (73 per 1,000 deaths of all causes)                                       | 33,6  |
| Diarrhoea and enteritis ... 37 per 1,000 deaths of all causes                                   |       |

The actual causation is not therefore established in two latter groups, and every practical diagnostician cannot but admit that a fair proportion of these cases in industrial areas are tuberculous, more so than cases wrongly diagnosed as tuberculous. These missed cases and the contacts new come under the vigilance of the tuberculosis staff.

The inference from the facts as to sickness and invalid in the Ministry's report is equally conclusive. Of 36, in cases of illness collected by the Regional Medical Officer from 226 insurance practices of 116 towns, tuberculosis only diagnosed in 505 cases (13.9 per 1,000 of total cases); bronchitis and bronchial catarrh in 7,739 (213 per 1,000); The ratio per 1,000 total cases for pneumonia and of respiratory diseases was 14.8; digestive system 13; debility, neuralgia, and headache 55. Here again

up (representing ventricular diastole) and down the ladder (representing ventricular systole); normally (i.e. normal ventricular cycle) the bucket goes up to the top and down to the bottom of the ladder; but abnormally (i.e. Fractional Heart EXPANSION and CONTRACTION) the bucket may only go up 3 or 5 or 7 or 8 etc. rungs and then come sharply down to the bottom again. On the other hand the bucket may go up to the top (20th rung) of the ladder (i.e. full ventricular diastole) and then only come down to the 15th or 14th or 12th etc. rung (representing Fractional ventricular Systole) before going up to the top again. These "bottom" Fractional beats e.g. (1st to 5th rung) and "top" Fractional beats e.g. (20th to 15th rung) represent two types of Fractional contractions at either end of the Cardiac cycle scale, occur more or less indiscriminately in Cardiac failure, are irregular and mixed with occasional complete ventricular systole and diastole. Fractional contractions are in my opinion Nature's far-seeing efforts to rest the Heart muscle for the complete heart-contraction which it wants to give every time. I disagree with many other assertions of Dr. Meakin about the Heart but I don't like 5 minutes letter writing to put my views into what it took me 5 years' study of the Heart to find out. Perhaps if Dr. Meakin studies my booklet it may shed new light on the heart for him.—Yours sincerely,

MICHAEL BERCHMANS SHIPSEY, M.B., B.Ch.

403, Slade Road, Erdington,  
Birmingham, 25.6.23.

### THE EXPERIMENTAL INQUIRY INTO THE CAUSES OF CANCER.

SIR,—I have read with the greatest interest the very able article on cancer by Dr. Leitch of the Cancer Hospital Research Institute (July 7th, p. 1).

It displays the broadest and most searching induction I have come across for a long time. It is bound to be of great service to those whose time and opportunities do not permit them to pursue such experiments as fall to the lot of Dr. Leitch and his colleagues.

There is one point throughout all the experiments with externally applied irritants which strikes me forcibly—namely, that they produce only epitheliomatous conditions. Do those locally produced epitheliomata later on produce constitutional cancer which may become diffused independently of the locally induced cancer?

I can quite understand locally induced cancer spreading and producing poisonous effects, but not in the same manner as other cancers. In my opinion, locally induced cancer is caused by the long continued exclusion of the air and the enclosure of epithelial excretion which destroys the cells and is bound to produce a backward tendency of the poison produced. This is shown by the influence produced by the irritant continuing to travel after the irritant has ceased to be applied. In my opinion its method of attack is similar to syphilis, which takes a definite time to reach the germ plasma before it expresses itself on the skin, and it is rather curious that syphilis first attacks the same part of the germ plasma which is associated with all cancers. They seem to reach the germ plasma by something like a retrogressive contiguity. In my opinion all cancers are a reversion towards an embryonic condition. The nearer the cancer cells are to embryonic cells the more rapid the progress of the disease.—I am, etc.,

Bolton, July 16th.

A. W. CRAWFORD, M.B., C.M.

THE Accademia Medico-Fisica of Florence is preparing to celebrate next year the hundredth anniversary of its foundation; it is proposing to publish a souvenir volume giving the history of the progress of medicine as reflected in the proceedings of the society.

APPLICATION has been made by the State attorney-general of Richmond, Virginia, U.S.A., for revocation of the charter of the "Oriental University" of Cherrydale, Virginia. It is said that the federal authorities of the United States have had this "school" under observation for some time, and that if its charter is revoked the institution will be prosecuted for using the Post Office mails to defraud. Apparently degrees of all kinds are being sold both in the United States and abroad, and the names of prominent men now dead have been included in the university staff. The head of the "school" claimed, it is said, that by virtue of his ability as a medium he could get into touch with these dead members of the staff.

## Universities and Colleges.

### CONJOINT BOARD IN ENGLAND.

#### DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.

THE following regulations for the Diploma in Laryngology and Otology (D.L.O.R.C.P. and S.Eng.), drawn up by the Committee of Management of the Examining Board of the Royal College of Physicians of London and Royal College of Surgeons of England, after conference with various teachers in the subjects, have been approved by both Colleges and have now come into effect.

#### REGULATIONS.

I. Both parts of the examination will be held in the months of June and December.

II. The examination shall comprise:

Part I. (a) The anatomy, embryology, and physiology of the ear, nose, pharynx and larynx. (Candidates will be expected to be acquainted with the vascular, lymphatic, and nervous connexions of these parts and with the central nervous system in so far as it relates to the special regions concerned.) (b) Elementary acoustics.

Part II. (a) The recognition and use of special instruments and appliances. (b) The medicine, surgery, and pathology of the ear, nose, pharynx, and larynx.

III. The examination will be written, oral, and practical in Part I, and written, oral, practical, and clinical in Part II.

IV. Candidates may enter for Part I of the examination at any time after a registrable qualification in medicine, surgery, and midwifery has been obtained. (Candidates must present themselves for the whole of Part I. In the event of failure in one division only, candidates will be allowed to present themselves for re-examination in that division.)

V. Candidates may enter for Part II of the examination on the completion of one year of special study of diseases of the ear, nose, pharynx and larynx, after a registrable qualification in medicine, surgery, and midwifery has been obtained, provided that Part I has been previously passed, and on production of the following certificates:

(a) Of having attended the laryngological and aural clinical practice of a recognized hospital or of the laryngological and otological departments of a recognized general hospital for twelve months. (The conditions of this certificate (a) will be fulfilled by holding the appointment as house-surgeon or house-physician or as clinical assistant at one of the above hospitals or departments, provided that in the case of a clinical assistant the certificate shows that he has attended for at least three hours a day on two days of the week.)

(b) Of having attended operations to the satisfaction of the surgeons in charge.

(c) Of having received instruction in pathology and bacteriology with special reference to laryngological and otological medicine and surgery.

VI. The fee for admission or readmission to each part of the examination is £66s.

VII. Candidates must give fourteen days' notice in writing of their intention to present themselves for examination, to the Secretary at the Examination Hall, 8-11, Queen Square, Bloomsbury, London, W.C.1. In the case of Part II the necessary certificates of study must be produced with the notice.

VIII. Graduates in medicine or surgery of Indian, Colonial, and foreign universities recognized by the Examining Board in England, but whose degrees are not registrable in this country, may enter for the examination for the Diploma in Laryngology and Otology on fulfilling the same conditions in regard to study.

IX. The above conditions of study may be modified at the discretion of the Committee of Management in the case of a candidate (a) who has carried out original investigations, or has written a thesis on some subject in laryngology or otology; (b) whose studies have extended over a prolonged period of time without fulfilling the exact conditions; but exemption will not be granted from any part of the Examination.

#### Syllabus of the Examination.

*The Ear.*—Congenital deformities. Wounds and injuries. Foreign bodies and parasites. Acute and chronic inflammations and their complications. Simple and malignant new growths. Deaf-mutism—verrucae—tinnitus. Tuberculosis. Syphilis. Simple and malignant new growths.

*The Nose and Pharynx.*—Congenital deformities. Injuries and foreign bodies. Acute and chronic inflammation; vasomotor rhinitis; retro-pharyngeal abscess. Nasal obstruction; adenoid growths. Acute and chronic inflammation of the nasal sinuses. Diseases of the tonsils. Tuberculosis; syphilis. Simple and malignant new growths.

*The Larynx.*—Congenital deformities. Injuries and foreign bodies. Acute and chronic inflammation. Disorders of innervation, sensory and motor. Tuberculosis; syphilis. Simple and malignant new growths.

*Note to Syllabus.*—Candidates will be examined on radiograms; and also will be expected to recognize under the microscope and growing in or on nutrient media the organisms common to infections of the above regions.

For Part I two examiners will be appointed by the Royal College of Surgeons; for Part II one examiner will be appointed by each College.

The Committee will, subject to an annual report to the Colleges, determine the courses to be specially recognized as fulfilling the conditions of the Regulations.

II.—Mrs. ELEAN F. PINSENT,  
Commissioner of the Board of Control.

THE Mental Deficiency Act has now been in existence nearly ten years, and it may be interesting to give some account of the work which has been accomplished under its provisions. This Act was based to a large extent on the findings of the Royal Commission on the Care and Control of the Feeble-minded, and it will be helpful towards understanding the problem to quote one or two passages from their report. The Commissioners stated that they were compelled by the experience to come to the conclusion

"that there are numbers of mentally defective persons whose training is neglected, over whom no sufficient control is exercised, and whose wayward and irresponsible lives are productive of crime and misery, of much injury and mischief to themselves and to others, and of much continuous expenditure wasteful to the community, and to individual families."

The report says:

"We find a local and 'permissive' system of public education, which is available, here and there, for a limited section of mentally defective children, and which, even if it be useful during the years of training, is supplemented by no subsequent supervision and control. We find large numbers of persons who are committed to prisons for repeated offences, which, being the manifestation of a permanent defect of mind, there is no hope of repressing, much less of stopping, by short sentences. We find lunatic asylums crowded with patients, who do not require the careful medical treatment that well equipped asylums now afford, and who might be treated in many other ways more economically, and as efficiently. We find, also, a large in the population many defectively

It is seen, therefore, that the main principle which stands prominently in the report and recommendations of the Royal Commission is that to secure adequate treatment of the mentally deficient there must be unity and continuity of care and control. The object of this paper is to show how far it is possible to carry out this policy under the provisions of the Mental Deficiency Act.

Except in a small percentage of cases it cannot be said that the Mental Deficiency Act is at present exercising unity or continuity of control, though it undoubtedly aimed at creating the machinery by which these conditions could be secured. It established one central authority, the Board of Control, for the "general superintendence of matters relating to the supervision, protection and control of defectives," but the Act did not hand over all defectives to the Board's care. Children up to the age of 7 can be dealt with under the provisions of the Mental Deficiency Act; from 7 to 15 the Board of Education is responsible for feeble-minded children; after 16 those needing further care can be dealt with by the Board of Control. The Home Office is responsible for those dealt with under the Children's Act and also through the prison service for adult mentally defective

of those great French physiologists Bernard, Pasteur, Marey, and Chauveau. His researches on the physiology of muscle and nerve, on respiration, on the mechanism of the flight of birds, on immunity, fermentation, and numerous other subjects would, in any case, have placed him in the first rank of experimental physiologists. But the crowning discovery of his physiological career was the production of anaphylaxis. Professor Richet's original experiment might be described as of quite a humble nature. He had made an extract from the tentacles of a sea anemone and injected a small amount of this extract into mammals. The effect of the first injection had been almost nil, but on repeating the dose some weeks later a condition of profound shock had resulted, followed in many cases by death. Such an effect had been known to occur after the injection of serums in the prophylactic treatment of disease, and although the causation of anaphylaxis was not yet completely understood, Richet's experiments had greatly helped towards its elucidation and had opened up an entirely new field to the pathological physiologist.

There was no more famous name in modern physiology than that of IVAN PETROVICH PAVLOV. His investigations upon the digestive organs and the conditions under which the secretions not upon the food were poured out marked an epoch in the physiology of this subject. Previous to his work little or nothing was known of the nervous mechanism regulating the secretion of gastric and pancreatic juice. Pavlov's investigations threw a flood of light upon a hitherto obscure subject and formed the starting point for all future work upon it. A still more remarkable series of researches were those dealing with the so-called "conditioned reflexes." Pavlov had shown in his earlier researches that psychical influences had an important and strictly measurable effect upon the flow of both saliva and gastric juice, but his experiments penetrated a long way further into the obscure region which connected physiology and psychology.

#### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following fifteen successful candidates, out of forty-six entered, who passed the requisite examinations, have been admitted Fellows:

T. Ahmed, R. C. Beeg, W. E. R. Coad, A. Denham-White, M. J. Gibson, C. Gill-Carey, H. M. Godfrey, A. W. Harley, F. Harvey, A. T. Hawley, N. E. Kendall, J. S. Lloyd, D. M. MacLeod, Gladys H. Marchant, L. D. Mercer.  
D. N. Bhaduri and H. C. van Dort have been admitted Licentiates.

### Obituary.

G. I. THOMPSON STEWART, M.A., M.D.,  
M.O.H. East Suffolk.

WE regret to announce the death, which took place suddenly on July 15th, of Dr. George Irvine Thompson Stewart, second surviving son of the late Sir David Stewart of Banchory-Devenick.

Dr. Stewart, who was 51 years of age, graduated M.A. Aberdeen in 1893, M.B., C.M. in 1896, B.Sc. with highest honours in medical sciences in 1899, and M.D. in 1912. After holding the appointment of senior house-physician under the late Dr. Angus Fraser Dr. Stewart went in for surgical work in the hospitals in London, Berlin and Vienna; he took the F.R.C.S. Eng. in 1906. He was the chief assistant for three years in the throat department of St. Thomas's Hospital, and senior clinical assistant at the Throat Hospital, Golden Square. As house-surgeon and surgical registrar at the Great Ormond Street Hospital for Sick Children Dr. Stewart became interested in children, and was appointed in 1908 school medical officer for East Suffolk. His work there received special commendation from the Board of Education, and his annual reports have been extensively quoted in the Blue Books issued by the Chief Medical Officer of the Board. In 1911, after taking the D.P.H., he was appointed county medical officer of health as well. He threw himself with characteristic energy into the work of his departments. He was genuinely admired by his staff and colleagues not alone for his outstanding abilities as a public administrator but as a man of generous heart and disposition, ever ready to spend himself in the interests of others and to promote and foster good fellowship among the staff engaged in the service of the county.

As secretary of the South Suffolk Division of the British Medical Association he put the branch on a firm footing and his loss will be greatly felt. In 1917 he became adjutant of the local unit of the R.A.M.C. (Vol.), and later when the Defence Force was created he assumed charge of the R.A.M.C. sanitary section.

#### FLORA MURRAY, C.B.E., M.D., D.P.H.

THE death of Dr. Flora Murray on July 28th, in her 54th year, removed one who will long be held in grateful remembrance by the sick and wounded who were under her care during the great war. Dr. Murray was a student at the London (Royal Free Hospital) School of Medicine for Women, and at the Royal Infirmary, Newcastle. She qualified in 1903 with the M.B., B.S. degrees of Durham University, proceeded M.D. in 1905, and she obtained the D.P.H. Cambridge in 1906. Dr. Murray was especially interested in children and held the appointment of physician to the Harrow Road Children's Hospital, and was also clinical assistant at the Belgrave Hospital for Children. She wrote an article on ethyl chloride as an anaesthetic for infants, in the *Lancet*, 1905, and was anaesthetist at the Chelsea Hospital for Women. In 1912 she was one of a group of eager women who started the little Hospital for Children in Harrow Road.

As soon as war was declared Dr. Flora Murray, together with Dr. Louisa Garrett Anderson organized plans for helping, and gathered round them other enthusiastic women. The immediate result of these plans was the formation of the Women's Hospital Corps, which was the first of the women's voluntary units. Although the corps consisted originally of only twenty members—doctors, orderlies, and nurses—their offer of help was readily accepted by the French Government and work was immediately started in Paris. Later, the corps was asked to start a hospital of 200 beds at Wimereux; this hospital was afterwards taken over by the R.A.M.C. Sir Alfred Keogh then proposed to the corps the organization of a women's military hospital of 550 beds in London. The old St. Giles's Union Workhouse in Endell Street was taken over and equipped, Dr. Flora Murray being placed in charge. The medical staff were graded for pay as members of the R.A.M.C., women orderlies were employed, nurses being attached to the Q.A.I.N.S. The work which was achieved by this hospital and by the corps previously is recorded in Dr. Flora Murray's book published in November, 1920, entitled, *Women as Army Surgeons: being the History of the Women's Hospital Corps in Paris, Wimereux, and Endell Street, September, 1914, to October, 1919*. The official recognition of her services was the award of the C.B.E. The affectionate gratitude of the sick and wounded soldiers who passed through her hands is a great testimony to Dr. Murray's work.

### Medical News.

THE Rockefeller Foundation has arranged to present to the German universities five copies each of the principal British and American medical journals. One copy will be given to the State library of Berlin or Munich and the other four will be distributed among four groups in the north, south, east, and west of Germany, each of which contains five or six universities. A journal will remain in the library of each university for two months.

A NEW medical periodical, the *British Journal of Anaesthesia*, appeared at the end of last month. It is conducted by an editorial board of twelve anaesthetists in various centres in Great Britain and is edited by Dr. H. M. Cohen, anaesthetist St. Mary's Hospitals, Manchester. It is to be published quarterly by Messrs. Sherratt and Hughes of Manchester. The annual subscription is £2, post free; the price of single copies is 10s. 6d. The first number contains 54 pages, and consists of original articles and abstracts, and a bibliography of current literature; there are also some notes on societies. One of the papers is by Drs. Gwathmey and E. P. Donovan of New York. It deals with painless childbirth by synergistic methods. By "synergistic anaesthesia" is meant "the reciprocal augmentation of the action of one or more drugs upon one another with unconsciousness." "Synergistic analgesia" is the term employed when consciousness is present. Dr. Gwathmey states that when the agents are properly selected and used the "effect is much greater than the simple summation of their pharmacological action." The aim appears to be the diminution of pain without loss of consciousness. The solution is administered by the rectum and is believed to reach the colon. A number of formulas are given. That which appears to be preferred contains urea 1 per cent.,

has at present been made of this section. The mental hospitals still contain large numbers of congenital cases who could be better dealt with in colonies for the feeble-minded.

This is partly due to the want of such accommodation, but not wholly, as there are still vacancies in certified institutions approved under Section 27 of the Act. It is also due to visiting committees not appreciating their powers under this section and to lack of complete co-operation between the visiting committees and the local authority. Consequently a number of congenital defectives are discharged from mental hospitals, and though probably all do not require further institutional care, it would be an immense advantage if they could be brought into touch with the local authority and placed under friendly observation or supervision—a procedure which would tend to prevent a return to the mental hospital. In order, then, to link up the means of affording such cases help and care and to secure continuity, the mental hospital should inform the local authority of the discharge of mental defectives from mental hospitals.

A valuable amount of protection and care can be afforded to defectives by Sections 8 and 9. These establish a procedure whereby mentally defective persons proved guilty of offences may, in lieu of sentence, be sent to an institution or placed under guardianship, and whereby defectives detained in a reformatory or industrial school or undergoing sentence in prison may be transferred to a certified institution. Action taken under these sections is unfortunately often too late to prevent young persons from contracting anti-social and vicious habits, but it may be in time to prevent them from becoming habitual criminals, and in the case of youthful offenders it affords an early starting point for the continuous care for which their mental condition calls.

At the close of 1922 the number of cases remaining in institutions who had been dealt with under Sections 8 and 9 was 1,512. This figure represents a gradual accumulation since the year 1914, but no particulars are available of the total number of such cases admitted since that date. It is difficult to form an idea as to the proportion this number bears to the actual number of mentally defective criminals, but it is interesting to observe that the medical investigators appointed by the Royal Commission estimated that at least 10 per cent. of the prison population were mentally defective.

Dr. Fiedgold approaches the matter from a different standpoint, and concludes that at the date of his investigation in 1906 there were probably between 12,000 and 13,000 inmates with pronounced criminal and anti-social tendencies in England and Wales. It may fairly be concluded that there are still a large number of mentally defective persons who are discharged from time to time from prison without the protection afforded by the Mental Deficiency Act. Here again a great deal might be done by further co-operation between the medical officers of the prisons and the medical officers of the local authorities. If for any reason an order under Section 9 is not made it would be a great advantage if the local authority could be informed of the discharge so that the defective could be kept under supervision and prevented if possible from a return to criminal courses.

Under Section 30 (a) of the Mental Deficiency Act it is the duty of the local authority to ascertain what persons within their area are defectives subject to be dealt with. The returns of the local authorities as to numbers vary greatly. Some authorities have not ascertained in one case, while the greatest proportion ascertained in one area is 3.50 per thousand. It is probable that in some districts the search for defectives has either not been made, or made in a perfunctory manner. Though no reliable estimate can be given for the whole population, the following figures are of interest.

The urban and five rural areas were selected in which the largest proportion of defectives have been found. The total number of defectives ascertained is 5,793, or a ratio of 1.65 per thousand. The five rural areas have a combined population of 1,214,730. The total number of defectives ascertained is 2,286, or a ratio of 1.88 per thousand. If similar proportions obtain in the whole of England and Wales as in the above ten areas the estimated

This is still far below the figures given by the Royal Commission, who estimated that there were 149,688 defectives, 64,783.

number of defectives to be ascertained works out at 64,783.

But it is difficult to compare these figures, for the following reasons: (1) The Royal Commission's estimate included all the ages of 7 and 16 do not come within the jurisdiction of the local authorities. As has been stated above, the report of the Board of Education shows that 31,000 school children have been ascertained to be mentally defective, and this is undoubtedly far below the number that actually exist. (2) The Royal Commission's findings included a large number of defectives in Poor Law institutions. These are not ascertainable under the Mental Deficiency Act, and it is not possible to obtain accurate figures, but it is known that a very large number of the inmates are mentally defective, and to these must be added those in receipt of outdoor relief. The total number ascertained by local authorities on January 1st, 1922, was 25,470, or 0.67 per thousand of the population. It is therefore highly probable that a very large number of defectives exist for whom the Mental Deficiency Act has not yet provided any measure of care, training, and protection.

Section 30 (b) imposes on local authorities the duty of providing "suitable supervision" for defectives who have been ascertained to be subject to be dealt with under the Act. The manner in which, and the extent to which, this duty has been carried out leave much to be desired. Some local authorities have actually no cases under supervision, while others are making great use of this method of protection and care.

The latest available figures show that 9,854 defectives were under statutory supervision on January 1st, 1922. It is difficult to determine how far this supervision is effective in affording adequate protection, and there is reason to believe that its usefulness varies enormously with the personal equation of the supervisor. The usual method is to secure periodic visits to the defective at home, and reports of these visits are presented to the local authority. Sometimes the local authority employs a visitor engaged directly for the purpose, and sometimes delegates the whole of the supervision of defectives to a voluntary association. Both methods, if wisely carried out, are successful. In other instances we find that local authorities rely on visits made by relieving officers or the police or by sanitary inspectors. Better results would be obtained if the visits were paid by a symphonic understanding of the conditions of the homes and a knowledge of the mentally defective. Whenever possible, these women should be given a short course of training such as that organized by the Central Association for Mental Welfare. The importance of obtaining for this work persons of good judgement and with the requisite experience cannot be overestimated, particularly when we remember that it becomes their duty to report to the local authority whenever "superintendent or institutional care is advisable. It is of primary importance that the confidence of the parents should be gained, and to do this visits must be frequent and conducted with the greatest tact and sympathy.

Section 30 (d) imposes on local authorities the duty of making provision for the guardianship of defectives. This is a means of protection and care for those under order but whose condition does not call for institutional treatment. At the close of 1922 there were only 370 under guardianship, showing that comparatively little use had been made of this form of treatment. The reasons which deter local authorities from taking this course appear to be, first, the difficulty of finding suitable guardians, and, secondly, the belief that if a defective is suitable for family life, supervision at home will afford sufficient protection. There is much evidence to show that this is incorrect. There are a number of defectives who have no home, and many others whose homes are most unsuitable and whose parents are unable to exercise adequate control. It is a pity that there has been no organized effort to increase the number of cases dealt with by guardianship. It would be possible for a large

## INCOME TAX.

"R. A. B.," New Zealand, arrived in England in April intending to return. What is his position as regards income tax?

He becomes liable as from the time he reached the United Kingdom if he remains here for six months of the financial year ending April 5th. His liability would include tax on his earnings and on income brought to or received in the United Kingdom, subject, of course, to the usual allowances.

"Y. Z. X." inquires up to what date, from April 5th, in the financial year may a person reside in England and not be liable to tax, where the present residence is in England but the intention is to reside permanently abroad.

There is no such date. A person residing in the United Kingdom is liable up to the date of his departure. "Y. Z. X." has been misled by the different case of a person coming to this country for a temporary purpose only.

"J. P. M." is resident abroad, having a Colonial salary and income from this country consisting of (a) War Loan interest received untaxed and (b) income taxed before receipt from other investments.

He can claim repayment—assuming he is a British subject—on a proportion of the allowances, according to the ratio of his taxed British income to his total income. The claim can be made to the Chief Inspector (Claims), Cecil Chambers, 86, Strand, W.C.2, to whom preliminary application should be made for the appropriate form of declaration.

"PERPLEXED" has attended a retired medical practitioner and his family constantly; he has never sent in an account for professional services, but has received a cheque from the retired practitioner with the remark that it is sent "as a gift." Is he liable to tax on it?

The view of the courts, as brought out in the case of *Cooper v. Blakiston*, appears to be that the liability depends on whether or not the payment is made for services rendered, with whatever expressions it may be attended. If our correspondent had been put to any expense—for example, petrol or drugs—in attending this retired practitioner and his family, would he not have excluded such expenses in making up his statement for taxation? Our correspondent may be able to decide the question for himself in the light of the foregoing.

"FORMOSA" asks: If the value of a purchased practice increases during the first year of the buyer's tenure, can the Inland Revenue demand figures and assess the buyer on his figures in place of the predecessor's average for the previous three years?

No; where one person succeeds to a practice the successor is liable on the three years' average profits of the practice. This would not necessarily cover the case of appointments held by the buyer but not by the seller. If the Revenue authorities rely on any special circumstances of the case perhaps "Formosa" will explain their nature.

## HOMES FOR MENTAL CASES.

"J. R. L." asks what steps should be taken to regularize the position of the case of an old lady suffering from bodily weakness and delusions of suspicion; she is without means, but has been placed by friends in a nursing home where the matron receives her at a reduced fee. Our correspondent asks whether, if certifiable as of unsound mind, she can remain in a nursing home.

A patient who is certifiable as of unsound mind can be treated in a nursing home only if she is certified as a private patient in the usual way. The conditions under which a "single patient" may be received in a private house not licensed for the reception of lunatics are fully explained in Archbold's *Lunacy and Mental Deficiency*, fifth edition, pp. 578-586. Without lunacy certificates it is illegal for a person certifiable as of unsound mind to be treated in a nursing home, and the matron renders herself liable to prosecution even though she has taken her at reduced fees for charitable reasons. A patient in a nursing home who becomes certifiable should either be removed to the care of her relatives, certified and sent to a mental hospital, or certified as a "single patient" and the treatment continued in the home.

"INQUIRER" wishes to hear of a charitable institution where a certifiable insane gentlewoman can be received for a payment not exceeding £30 a year.

We do not know of any charitable institution taking mental cases certifiably insane for the sum indicated. Many county and borough mental hospitals take private cases, but since the cost of the pauper patients is greatly in excess of £30 per annum, the private patients could not be taken for a sum less than the pauper maintenance rate.

## LETTERS, NOTES, ETC.

The editors of the *Medical Directory* (7, Great Marlborough Street, London, W.) write: "The annual circular has been posted to every member of the medical profession. Most of the returns have already been received." They state that if any practitioner has not yet sent them the latest information they will be glad to receive it by an early post.

## THE RADIOGRAPHIC LOCALIZATION OF SPINAL LESIONS BY SICARD'S METHOD.

MR. PERCY SARGENT, in the interesting note on the mechanical method for localization of spinal lesions devised by Professor Sicard published at page 174, states that the oily fluid used consists of "huile d'oeillette," containing 40 per cent. of iodine and remarkably opaque to the x rays. "Huile d'oeillette" is official in the *French Pharmacopoeia*; it is used as the basis of a number of preparations described therein. It is made from the seeds of *Papaver somniferum*. An examination of the oil by Martindale (*Extra Pharmacopoeia*) showed that it contained no narcotic nor alkaloidal constituents. It is in fact so largely used for mixing with olive oil to produce a salad oil that it has almost ceased to be regarded as an adulterant. The maximum amount of iodine that can be dissolved in the oil depends upon the "iodine number" of the oil; 40 per cent. is quite feasible in some instances, but the preparation must be carefully made. It is an additive compound of poppy-seed oil and iodine.

## EPITHELIOMA CONTAGIOSUM OF FOWLS.

COLONEL MCCARRISON, in relating the experiment which forms the basis of his interesting paper published at page 172, mentions the constituents of the diet upon which pigeons at Coonoor can be maintained in perfect health in captivity, but he does not explain the meaning of the terms he uses. We have, therefore, made some inquiries of Colonel D. G. Crawford, who informs us that *dal* is the name given in India to all sorts of pulses. *Mung dal* is a regular item of jail dietaries, and as served out is very like the split peas sold in this country. *Green mung dal* probably means green lentils. *Ragi* is a coarse millet. *Cholim* is probably the same thing as *chola* or *gram*; it is another variety of pulse, *Cicer arietinum*. It is generally used in India for feeding horses, but is sometimes eaten by man. It is the *cicer* or chickpea which Horace speaks of.

## SKIN DISEASES IN ARMIES IN THE FIELD.

"CITIZEN SOLDIER" writes to take exception to a statement in the review of the second volume of the *Medical History of the War: Diseases of the War*, published in the *JOURNAL* of July 14th, page 66. The statement was to the effect that skin diseases as a cause of wastage did not gain the notice demanded until Colonel Soltan drew up in 1917 his memorandum on the classification of admissions to hospitals in the Second Army in France. Classification of causes of all admissions to hospitals was, our correspondent states, carried out systematically in that army from the first week of its formation by instruction of the D.M.S., Major-General Sir R. Porter, K.C.B., and was the subject of a weekly routine return which was circulated for information. The importance of preventable skin disease as a major cause of wastage was recognized and practical steps for repression considered by conferences held under the presidency of the D.M.S. This policy had been carried out even before Colonel Soltan's predecessor, the late Sir James Galloway, had been appointed consulting physician. The fact that wastage due to skin diseases was mainly preventable was recognized by the general staff, and the suitable technical measures recommended by the medical branch were carried out by the quartermaster-general's branch. Save for a few quiet periods the Second Army was a continually expanding force, with a narrow front of only twelve miles, behind which at the battle of Passchendaele lay over 800,000 men. The organization concurrently developed in the field for combating disease, preventable skin diseases among others, therefore involved a vast organization.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 26, 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 92.

## SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 6  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 15 0 |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference to the Post Office to receive *postes restants*.

Note.—It is against the rules of the Post Office to receive *postes restants* letters addressed either in initials or numbers.

The argument contained in these few observations may be stated briefly as follows: By segregation of the insane, large number of persons who are a potential menace to the community; and by so doing we prevent in some degree the propagation of the unit, though unfortunates that those whom it is easiest to segregate. There remain those who are most unlikely to propagate. There remain

## 94. The Minimum Fatal Dose of Veronal.

B. FELDEN (*Deut. med. Woch.*, June 22nd, 1923, p. 822) reviews the literature of veronal fatalities, and draws attention to a case reported by Bofinger in which a man, aged 25, died after taking only 4.5 grams. In 1922 Renner collected 26 published cases, all of which terminated fatally, and in none of which the dose was less than 10 grams. In his textbook of pharmacology Poulsson states that doses of 8 to 10 grams are necessary to prove fatal, and Tappeiner has found only doses of 5 grams or more to prove fatal. The author himself records the case of a perfectly healthy woman, aged 24, who took 5 grams with a view to committing suicide, and who suffered no ill effects therefrom. If this case be contrasted with that of Bofinger's fatal case, the conclusion is inevitable that idiosyncrasy or susceptibility on the part of the individual greatly affects the issue, the reactions of various persons to one and the same dose of veronal differing greatly.

## 95. Nephritis in Enteric Fever.

J. CHALIER and R. DESJACQUES (*Paris méd.*, June 2nd, 1923, p. 503), who report a personal case, remark that in a considerable number of cases (Murchison 25 per cent., Griesinger 1 per cent., Gubler and Robin, Trotter 100 per cent., Challer and Desjagues 35 per cent.) albuminuria may occur in enteric fever at the height of the disease without any other signs of renal involvement, and disappear in convalescence without leaving any trace. Typhoid nephritis properly so called is that which occurs either as an initial symptom in the rare cases of nephrotypoid described by Lesieur, Gouget, Ourschmann, and others, or, much more frequently, in the course of a definite attack of enteric fever, as in the authors' case. Most authors are agreed that uraemic symptoms and oedema are very rare in typhoid nephritis. The prognosis is favourable in the great majority of cases. The albuminuria disappears completely in convalescence, and no trace of the renal lesion persists. Chronic nephritis is very rare. The present case occurred in a woman aged 21, who developed nephritis in the second week of paratyphoid B fever, accompanied by oedema, casts and haemoglobin in the urine, and retention of chlorides. The nephritis lasted twenty days, and cleared up completely without any sequelae.

## 96. The Abortive Treatment of Syphilis with Salvarsan.

U. MÜLLERN-ASPEGREN (*Hygiea*, May 31st, 1923, p. 421) publishes numerous statistics in support of his opinion that the best treatment for early syphilis consists of giving several large doses of salvarsan, and that one of the worst things the patient may suffer is to be given small doses of salvarsan, which favour, rather than check, the development of syphilis of the central nervous system. The author refers to the investigations of Gennerich in this connexion. His own statistics are as follows: Of 141 cases of primary Wassermann-negative syphilis given abortive treatment with salvarsan, only 4 showed a relapse, and in all 4 cases the salvarsan treatment had been timid. In other words, when at least three large injections of salvarsan are given in the Wassermann-negative phase of the first stage of the infection, 100 per cent. may be cured. It remains, however, to be seen whether, from twenty to forty years later, all these cures will be maintained. The author traced 81 of the 89 cases of primary syphilis treated with salvarsan after the Wassermann reaction had become positive. Eight were found to have relapsed, but only in 2 of these 8 relapses had the salvarsan been pushed vigorously. Of the 48 cases of early secondary syphilis treated with salvarsan, 7, or 15 per cent., were found to have relapsed, but among the cases treated with several large doses of salvarsan the incidence of relapse was only 9 per cent. The author's advice may thus be summarized: Give several large doses of salvarsan or abstain from it altogether.

## 97. "Tuberculous Rheumatism."

S. MAGNUSSEN (*Hospitaltidende*, June 6th, 1923, p. 409) criticizes as exaggerated and misleading the teaching of Poncet and his followers that many cases of polyarthritis, and most cases of chronic polyarthritis, are due to the tubercle bacillus; but although tuberculous articular rheumatism may be comparatively rare, the author has recently seen two very characteristic cases at his sanatorium in Iceland. The clinical picture is fairly well defined, but the disease does not run a uniform course. Its onset is often more or less acute, and its subsequent course is milder and more protracted than that of true rheumatic fever. The temperature is but little or not at all raised, the general health is but slightly affected, and the heart is seldom involved. It is characteristic of this form of acute polyarthritis that it is refractory to salicylates. There may or may not be an effusion into the joints, and while the disease may clear up in some joints, it tends to

settle in others, giving rise to fibrous ankylosis with the clinical picture of arthritis deformans. In the author's cases sanatorium treatment, supplemented by natural and artificial heliotherapy, effected considerable improvement.

## Surgery.

## 98. Localized Peritonitis in Paratyphoid Fever.

A. E. MORTIMER WOOLF (*Brit. Journ. Child. Dis.*, April-June, 1923, p. 91) reports a case of localized peritonitis due to intestinal perforation in paratyphoid fever B. The patient was a boy, aged 15, who developed acute abdominal pain on the fifteenth day of disease with tenderness in the right loin and right iliac region, where a mass could be felt. Operation was performed and a perforation was found in the lower end of the ileum walled off from the general peritoneal cavity by the great omentum. The perforation was closed and recovery was uneventful. Commenting on the case the author remarks that intestinal perforation in paratyphoid fever is rare. Of 1,038 cases of paratyphoid B in Webb-Johnson's statistics there were only three instances of perforation, or 0.29 per cent.; whereas in paratyphoid A perforation was commoner, there being two instances among 344 cases, or 0.85 per cent. On the other hand, Vincent and Muratet maintain that the infrequency of perforation in paratyphoid is only true in civil practice, as during the war both intestinal haemorrhage and perforation were almost as frequent in paratyphoid as in typhoid fever. The literature shows that when perforation occurs in typhoid or paratyphoid general peritonitis almost always results. Although there are a few cases on record of localized peritonitis due to typhoid, Woolf's case is apparently the first example of the kind occurring in paratyphoid fever.

## 99. Peptic Ulcer following Gastro-enterostomy.

HENRI BÉCLÈRE (*Journ. de Radiol. et d'Électrol.*, April, 1923, p. 161) points out that radiologists in many countries have been able to demonstrate in cases of peptic ulcer the presence of a diverticulum. In France this does not appear to have been shown so frequently, and he records a case where a diverticulum, only visible after repeated x-ray examination, was confirmed at operation. The patient, aged 39 years, suffered from constant pain and vomiting after food. Radiographic examination showed that pyloric stenosis was present, due to an ulcer. This was confirmed at operation and a gastro-enterostomy was performed. The patient improved and put on weight. Six months later examination showed a little fluid present in the fasting stomach and the anastomosis functioning well. There was a point of increased irritability on the jejunal loop with some delay and dilatation at this spot at certain times. Clinically there was persistent pain to the left of the mid-line, which increased after food, and vomiting. On palpation some thickening was detected to the left of the umbilicus. X-ray examination some months later showed increased irritability at the opening of the gastro-enterostomy and the contents passed less easily through the stoma. A diagnosis of peptic ulcer near the stoma was made. A series of plates were taken with an exposure of a fifth of a second, and a diverticulum in this position was clearly demonstrated. At the subsequent operation a peptic ulcer was found on the posterior lip of the stoma and a diverticulum was present. A partial gastrectomy was performed for this condition.

## 100. High Frequency in the Treatment of Fissures and Haemorrhoids.

C. SCHMITT (*Bull. Soc. de Thér.*, May 9th, 1923, p. 152) states that high-frequency currents possess anaesthetic, antispasmodic, haemostatic, and destructive properties which have been used with success in the treatment of fissure of the anus and haemorrhoids, as was first shown by Professor Doumer of Lille. Provided that fulguration is not employed, high-frequency currents are perfectly safe and do not require an anaesthetic. They also possess the advantage of not causing any interruption of the patient's occupation, as the application lasts only a few minutes and does not produce any disagreeable sensations necessitating rest in bed. In some cases improvement is immediate, and as a rule recovery takes place after four to eight applications, while in obstinate cases twenty to twenty-five are needed. Failures are rare if the treatment is properly carried out. Most of Schmitt's patients were persons of nervous disposition, and mostly colonials who had contracted dysentery and other affections of the large intestine during their stay in the tropics, their piles being accompanied by proliferation of the rectal mucosa. Schmitt also records a case of an enormous inoperable prolapse of the rectum in a man aged 83 which was successfully treated by high-frequency currents.

indication that the child can ever be looked upon as normal, or approaching to normal, then, in my opinion, and that of many others, especially in America, steps ought to be taken to prevent that child ever becoming a parent, for it is certain that the offspring would be defective. Although this simple operation should be carried out, care would not be relaxed in treatment, which would be carried on as usual.

With a number of these mental defectives segregation must be resorted to, and it is of the utmost importance that both males and females should be closely watched, so that they may not escape from control, for a girl runs the risk of conception, to be followed by an illegitimate child. It is quite extraordinary how prolific these mental defectives are, and they reproduce their kind from two to six times more rapidly than those who are normal. It may be thought such supervision is exercised that girls cannot escape from it, but we know that they do, and in those defective supposed to be well enough to be looked after by their relatives opposite result that the girl may repeatedly conceive, and bring forth many illegitimate children, who will in turn be mentally defective. In addition, they run the risk of venereal infection, and of spreading it indefinitely. In those girls who are slightly defective, and in the opinion of the mother or relative well enough to contemplate matrimony, the marriage is followed by the birth of mentally defective children. In my opinion there is only one way of doing really permanent good, and that is by sterilization of the mentally defective. This must be considered under (a) sterilization of children, and (b) sterilization of adults.

(a) Sterilization of Children.

If a child be found to be a mental defective it will have the care necessary, either from a private or public institution, for the act referred to is responsible, and, after the age of 7, Section 1 of the Elementary Education Act, 1914, provides for education. But supposing the child reaches the age of 16 to which I have referred, and in spite of all the time spent in its education and the attention devoted to its welfare proves to be mentally defective, with no hope of permanent improvement, in my view the child ought to be prevented later on from becoming a parent, and of being the means of bringing into the world children more or less defective.

Let me say at once that my suggestion is only intended for those upon whom every possible means of treatment has been tried, whether by education or segregation, so that it does not exclude treatment from the earliest moment by mental hygiene, the National Council for which is already doing so much good, and from whom so much is hoped. Needless to say, this sterilization would only be carried out after the subject had been passed by one or more alienists, and in any case with the least chance of improvement the age could be extended beyond 16. In the American States there are said to be 250,000 mentally affected in hospitals, with 50,000 admissions every year. Every precaution is taken when sterilization is carried out. In this country it would only be necessary to add a section to the present Mental Deficiency Act, making strict regulations to ensure the safeguarding of the subject. Now, having said that there is no question of sterilization in those cases in which there is any chance of the individual becoming normal, I maintain that sterilization is a perfectly humane method of treatment, for while still endeavouring after the operation, to do all in our power medically for the unfortunate subject, we also wish, for the sake of the State, to prevent the propagation of the unfit. This, from a State point of view, is of the greatest importance.

(b) The Sterilization of Adults.

For this a State certificate of marriage must be the first step, because, until a defective contemplates marriage, the necessity for sterilization does not arise, and it is evident that it would only be necessary in dealing with adults for a certain time, for if legislation is brought about there would be no need to discuss it, for the reason that all defective children would have been previously done. A

State certificate of marriage only means a medical certificate of health given to each about to marry. In the event of the *sporadic* *pulling*, gonorrheas, or tubercle bacilli being discovered, postponement of marriage could be adopted. But in the case of a feeble-minded man or woman, or those having such a family history of insanity as would render in the highest degree probably mentally defective a certificate. This prevents the unhappiness which forbidding marriage might cause, while at the same time guarding against the advent of children who might be a burden to the State. It would not increase illegitimacy, but for the percentage of women who would voluntarily risk illegitimate children, when marriage could take place, is small.

It is important to bear in mind, with reference to marriage, that all defectives do not want segregation or special control, and that it is not always easy to say at once that a man or woman desiring marriage is defective. Time does not permit me to go into this more fully now, but I would say that the only ones who can speak with authority on the subject are those who are continually working with them or the superintendents of institutions for the feeble-minded, and the latter assure us that, notwithstanding all that is done, the majority are never really cured. Dr. Paul Bowers, superintendent of the Northern Hospital for the Insane, Indiana, says that the degenerate, the feeble-minded, and the imbecile, will remain as they are, no matter how much we do for them, and that "this is the experience of all superintendents of institutions for feeble-minded."

Again, some people believe that modern civilization, by its Poor Law system and its treatment of the unfit during childhood, tends to foster the growth of this class. I maintain, however, that by sterilization, which does not change the life of the individual in the slightest degree, we can get rid of this class almost entirely, and as the years roll by there would be, as compared with the present day, little need for the operation, because we should have the advent of healthy children. It is certainly the safest and most effective course.

I have discussed this subject in favour of sterilization of the unfit, but naturally we all know well the difficulties of the world, and perhaps those in opposition to the suggestion base their opinion on sentimental grounds, and "interfere with the liberty of the subject." But it is right for that liberty to be encroached upon when it is a matter of health and the protection of the community, for when these defectives grow up they may become a danger to others, and the enormous advantage to the State of doing away with all these mental defectives cannot be weighed in the balance with any such arguments. We cannot get away from the fact that there are two-thirds of defectives whom we shall never benefit, but who have the power of rapidly reproducing their kind, who in turn become a burden and expense to the State. It is perfectly true that those who are segregated, and who are a danger to others, must still be guarded, but it is evident that in the end the vast majority of defectives would die out. I do not propose to sterilize the parents of mental defectives, for that would be retrospective, and those living at the time of legislation would in a few years have ceased to bring defectives into the world. I cannot see that it, amongst the many thousands of these defectives, occasionally one turns out to be a genius, it is any argument against endeavouring to prevent the propagation of the mentally deficient. It may be said that the Mental Deficiency Act requires amendment in various ways, and that if this act and the Defective and Epileptic Children Act were more effectively operated, improvement might occur; but the fact remains that, notwithstanding these acts, the proportion of mentally defective children to the entire population is undergoing a steady increase, and it cannot be denied that this is a serious social problem. Again, it may be argued that if segregation be efficiently carried out, it will be as effective as sterilization, and although we know that this would be true in the case of

**107. Treatment of Pernicious Vomiting in Pregnancy.**

C. L. URRIOLA (*Paris méd.*, June 16th, 1923, p. 544), during the last four years, has successfully treated all the cases of uncontrollable vomiting in pregnancy occurring in the Panama Maternity Hospital and in his private practice by subcutaneous injection of serum from the umbilical cord. The blood is taken from the umbilical cord after separation of the foetus and before detachment of the placenta, collected in a sterilized vessel, and placed in a refrigerator. Two drops of a mixture of formal and ammonia are added to each 5 c.cm. to keep it sterile, and its sterility is subsequently tested by repeated cultures and by injecting a few cubic centimetres into the ear of a rabbit. Urriola records eight illustrative cases in which the hitherto uncontrollable vomiting of pregnancy was cured by from one to three injections of serum from the umbilical cord in doses ranging from 2 to 6 c.cm.

**108. Disadvantages of High Caesarean Section.**

MARINACCI, in a report to the Accademia Medica di Roma (*Archivio di Ostetricia e Ginecologia*, May, 1923), relates the case of a woman whose previous pregnancy had been terminated during the ninth month by classical Caesarean section, and who during the fourth month of the ensuing gestation suffered from slight pyrexia and subacute dysenteric symptoms. Shortly afterwards acute abdominal pain and sudden collapse were noted, with contracted and tender uterus and exaggerated intestinal peristalsis; a diagnosis of rupture of the uterus and incomplete intestinal obstruction was made. At laparotomy it was found that a loop of small intestine was adherent to the uterus in the neighbourhood of the old hysterectomy scar; chorionic tissue had eroded the scar and penetrated the wall of the gut (this probably accounted for the dysenteric symptoms) and there was an extensive rupture of the uterus. The patient recovered after subtotal hysterectomy and enterectomy. The case is cited as an argument in favour of Caesarean section of the lower uterine segment.

## Pathology.

**109. The Titration of Antidiphtherial Serum by Flocculation.**

ACCORDING TO E. RENAUX (*C. R. Soc. de Biologie*, June 9th, 1923, p. 92) Ramon's method of titration of antidiphtheric serum by flocculation gives results differing by only 3 or 4 per cent. from those obtained by titration on the guinea-pig. The technique he employs is as follows: A standard toxin is used which has been filtered through paper and preserved under toluol. Its strength is such that it kills a guinea-pig of 250 grams in a dose of 1/300 to 1/400 c.cm. The serum and toxin are mixed in varying dilutions in tubes, which are placed in a water-bath at 37° C., care being taken to secure partial immersion only. The titre of the serum is judged from the first tube in which flocculation occurs. Using unbeaten serum this may be expected to appear after fifty minutes, but with serum previously raised to 56° C. for thirty minutes it is delayed for about four hours. The presence of 0.3 per cent. phenol in the serum makes no difference to the reaction. Filtration of the serum through a candle likewise has no effect on the reaction, but filtration of the toxin through a candle renders it more susceptible to flocculation.

**110. The Etiology of Tuberculosis of the Kidneys.**

G. EKEHORN (*Tubercle*, May, June, and July, pp. 337, 393, and 444) discusses in the Lennander lecture the etiology of renal tuberculosis. As he points out, it has for long been assumed that renal tuberculosis is a so-called "elimination" disease. According to this teaching, infection of the kidneys occurs because the tuberculous virus circulating in the blood has been excreted from the blood, through the kidneys, into the urine. The more this elimination theory is scrutinized the less plausible does it seem. It is common knowledge that the whole kidney is not infected simultaneously; gradually and over a long period the ulceration extends from one papilla to another. If the elimination theory is correct, what happens after nephrectomy to the bacilli supposed to be still circulating in the blood; whence do they go and where are they now eliminated? It is established that patients usually recover completely after nephrectomy for unilateral renal disease; after the operation neither bacteria nor other abnormal structures can be found in the urine. It is impossible to conceive how an elimination tuberculosis could be confined to one kidney, and if the elimination theory were correct, nephrectomy would not only be irrational, but directly injurious to the patient. In opposition to the elimination theory, which implies an indirect haematogenous

infection of the kidney, there is a theory according to which direct haematogenous infection is responsible for tuberculosis of the kidney, tubercle bacilli being deposited direct from the blood in a renal capillary. According to this theory, which the author endorses, tubercle bacilli are not first eliminated by the kidney and passed into the urine before they infect the kidney. They are deposited as a small embolus in a capillary of the renal parenchyma in which a tuberculous focus forms. This process is analogous to that which occurs when tuberculosis develops in the epiphysis of a bone; it is impossible to believe that the disease spreads in the bone because new infections from the blood give rise to new emboli. It is more natural to assume that the whole tuberculous process develops in both kidney and bone from a single primary focus of infection. As the author points out, the controversy over these two theories possesses much more than academic interest; according to the one theory operative treatment must be irrational, according to the other it is most rational.

**111. Endemic Plague in Russia.**

FURTHER evidence of the relation between human plague and the plague of rodents has been brought forward by D. ZABOLOVNY (*Ann. de l'Inst. Pasteur*, June, 1923, p. 618). In areas where plague is endemic, such as Mongolia, Transbaikalia, and the Kirghiz Steppes, extensive epidemics have been found to affect certain wild rodents—"tarabagans," ground-squirrels, and mice. The tarabagan (*Arctomys bobak s. sibirica*) is an animal which has a wide area of distribution; it lives in holes about three yards deep in the ground, and hibernates from September to April. In 1921 there was an epizootic amongst these animals, which was shortly followed by an epidemic amongst the people living in the country, starting with the hunters who seek the fur of these rodents. Similarly human epidemics have followed closely on epizootics occurring amongst mice and ground-squirrels. During the summer months it is the ground-squirrels which are responsible for the propagation of plague; during the winter, when these animals are in hibernation, it is mice which, taking refuge in human dwellings, form the source of infection. Camels likewise have been found to suffer from plague, and have been incriminated for the spread of disease amongst the population. Bubonic plague depends largely on the flea for its transmission; pneumonic plague on droplet infection.

**112. Rate of Sedimentation of Red Blood Corpuscles in Acute Infections.**

T. MIRONESCO (*Bull. et Mém. Soc. Méd. des Hôpitaux de Paris*, July 5th, 1923, p. 1022) has conducted some fresh studies on the old question of the significance of the varying rates of sedimentation of the red blood cells in patients suffering from acute infections. The tubes he used were 30 cm. long and 2.5 mm. in diameter; into these was placed the blood, which had been collected in a 3.8 per cent. solution of sodium citrate. The experiments were conducted at room temperature. In typhus, in typhoid fever, and in measles (the three diseases studied) an acceleration of the rate of deposit of the red cells was found, especially noticeable in the first. It was observed that not only in different cases of the same malady, but also in the individual case, fluctuations occurred which were in relation with the gravity of the disease. Further, a positive correlation was noted between the rate of sedimentation and the quantity of urea in the blood. There is apparently no specificity in the reaction; the changes in sedimentation do not depend on the nature of the disease; they coincide with other alterations, such as the degree of azotaemia.

**113. The Nature of the Bacteriophage.**

A FRESH experiment is recorded by F. D'HERELLE (*C. R. Soc. de Biologie*, June 23rd, 1923, p. 231) in support of the corpuscular nature of the lytic principle: 0.1 c.cm. of a 10<sup>-7</sup> dilution of a very active filtrate was mixed with an emulsion of Shiga bacilli in agar and poured into a Petri dish. After incubation the number of plaques which could be counted was 39. It is clear that if the bacteriophage exists in a corpuscular condition, and if each plaque represents the action of one corpuscle, then a 10<sup>-2</sup> dilution should contain 4 corpuscles. To verify this 10 c.cm. were taken and 1 c.cm. was put into each of ten tubes of bouillon, which were then seeded with young Shiga bacilli. As a result it was found that five of the tubes were clear and contained a very active principle, whereas the other five were turbid and showed a perfectly normal culture of dysenteric bacilli. It appears, then, that if a single corpuscle gains access to a tube it is able to prevent the growth of the organisms in that tube; if, on the contrary, no corpuscles are introduced, there is no inhibition of growth. This experiment, according to the author, demonstrates without any possible doubt that the bacteriophage is of a corpuscular nature.

a crime associated with defect, occurs comparatively rarely, only five times in a series of 500 consecutive criminal arrests examined by me. It has shown that every class of crime—except, in my experience, the rare crime of treason—is committed by defectives, and that the largest number are crimes of acquisition, sex, and vagrancy. I have mentioned frequently elsewhere the case with which a defective, having committed a criminal offence, forms a criminal habit; indeed, in certain cases it can be definitely stated that the offence will be repeated unless adequate treatment is adopted, but I mention it in this connection once again, for by early diagnosis and certification the criminal element is prevented from becoming a recidivist; and when it is remembered that a large class of cases form in prison it becomes manifest that the influence of the Mental Deficiency Act on crime will increase as time passes, and is being felt, indeed, already. In fact the amount of crime prevented by the Act is much greater than the actual figures suggest. It is in the prevention of crime by the early diagnosis and treatment of mental disease, disorder, and defect that the alienist can assist most usefully in attacking the criminal problem, and the importance of this cannot be exaggerated. Quite recently, of six men under my observation at the same time awaiting trial for murder, three were insane, and early diagnosis and treatment would have prevented the murders. And of those cases of defectives who have been under my observation charged with murder none presented difficulties in diagnosis to the expert examiner, and similarly with the majority of defectives who committed lesser offences. "The growing impotency of medical men to secure that the mental aspect of offenders is taken into account can only be fruitful if reliable results follow their recommendations. This requires an accurate perspective to be preserved, and it is essential not to expect results which are unobtainable. The Mental Deficiency Act was referred to at the Annual Conference on Mental Deficiency at Caxton Hall last year by Mr. Stuart Deacon, the superintendent magistrate of Liverpool, as "one of the greatest boons which the British Parliament has ever conferred upon His Majesty's subjects, and more particularly upon the poorer members of the nation." Medical men who work in criminal courts will be in entire agreement with this. So to-day has been the expression of a hope that over-enthusiasm should not endanger its constant application in the criminal courts.

C. MACFIE CAMPBELL, M.D.,  
Director, Boston Psychopathic Hospital, U.S.A.

ORGANIZATION FOR THE SUPERVISION OF MENTAL DEFECTIVES.

Dr. C. Macfie Campbell said that the hospital with which he was associated was somewhat similar to the Maudsley Hospital in London, and had 110 beds. Part of its responsibility, as in the case of all the State hospitals in Massachusetts, was to supervise the school population of a certain district and to see that all the children in that population, if there was any suspicion of mental defect, were systematically examined. It was part of the responsibility of teachers, and an opinion passed upon them. This work was not limited to the one township, but was now State-wide over the whole of Massachusetts. It had only lately been put into operation, and what the later social effects would be, how far they would be utilized, and what modifications might be necessary, was, of course, a matter for further experience to determine.

It might interest the Section to know what the procedure was. The diagnosis of mental defect was an important matter, although, as Dr. Porter had said, many judges on the bench felt that the natural common sense of the judicial mind was adequate for a diagnosis. In Massachusetts a somewhat elaborate investigation was made, in the first place, into the family history of each of the children and the stock from which the child had come, also the environmental factors and the school history. The medical man made a physical examination, and the teacher

a special investigation into the general information of the child. The psychologist also made a standard psychometric examination. On the basis of such an investigation a summary of the case was drawn up and the mental equipment of the child considered, and certain advice given. He showed the dossier of one child as a sample. This was a girl of 14, whose mental age was 8.8 and whose intelligence quotient, therefore, was 62 per cent. The child had reached the limit of her scholastic ability, and it was very doubtful whether she would profit by ordinary grade work. It was found that she had congenital syphilis. Her home situation was extremely poor; they therefore had to see that it was modified so far as it could be modified, and it was recommended that her training should be along special lines. What was the use of this sort of work? How were they going to translate it into practical terms? Was it worth while? It was a time-consuming affair. It meant that the physician spent several hours with each child, first on the physical examination and then on the correlation of various data; that the psychologist spent at least an hour with the child in going over the standard test; that the social worker had to have at least one interview with the parents; and that the school teacher devoted some time to the individualized study of the child. For each child there was formed a little clinic of six persons—on the hospital side, the physician, the psychologist, and the social worker; and on the school side, the school doctor, the school nurse, and the teacher. A certain number of the pupils brought forward were of such a grade of mentality or were constitutionally endowed so meagrely that obviously they required special care and attention. Up to now it had generally happened that those who had got special attention and care were not those separated out by systematic examination, but those who were a nuisance. The nuisance in life was always the one who got special attention, if not as a mental defective then as a spoilt child. If he was a mental defective he got an education which had some sort of relation to his mental equipment; he got what pertains in time all children would get, an education which had reference to his endowment and to what he was going to do afterwards. That principle might spread from the defective until presently it reached the universities! Perhaps most of what educationists had learned with regard to general education of recent years came from the defective child, so that in all this matter of special care they were merely returning something to him to which he was well entitled.

If these mental defectives had certain tendencies so had we. If the mental defectives was a potential criminal, John Bradford." And the grace of God in this instance so were we all. "There, but for the grace of God, goes the mental defective was a potential criminal, and social was translated into terms of nutrition, education, and social opportunity. What was it that made the child with poor opportunity drift into delinquent habits, the girl become an unmarried mother, the man a vagrant or an alcoholic? Take the history of the neglected defective child, grind-ling through the pedagogic mill, scolded because he could not learn what he was never meant to learn, disheartened because he could not keep up with the others, therefore escaping at every opportunity from school routine, becoming a truant, associating with all the undisciplined members of the school, and because of his defective mentality being made the tool of the unscrupulous and the ethically inferior—there one had the defective delinquent in the making. In his teens, guilty perhaps of repeated delinquency, he passed from the pedagogic into the judicial mill, and there was judged according to the statutes, and, having committed a certain crime, suffered its adequate punishment. The community was only just beginning to think that here was a human being whose circumstances and behaviour ought to be carefully studied before any course of action with regard to him was decided on at all. By the time such an individual had had several experiences with the courts one had the confirmed criminal, but this later career of his was along the grooves which had been determined by the social management of the case, not by the original endowment of the child.

and there were very few cases of intense poverty and neglect. There was a very striking contrast in the dependence on parish and charitable assistance among the families of the normal group on the one hand and of the insane and mentally defective groups on the other. The normals not only applied less often to the parish, but they were also less well known to charitable agencies. There was also, on the whole, a distinct difference in the degree of relief they received. "The normal cases more often than the other two groups relief was frequently sought for maintenance as well." It seemed, therefore, that not only very generally their immediate relatives also, were less capable of maintaining an independent existence than the relatives of the normal cases. Very composite pedigree charts of three or four generations of these groups of cases were made by Miss Kelley, and a typical pedigree chart was exhibited by Sir Frederick Mott.

Nearly ten years had elapsed since the results of this investigation were published. He hoped that either the Board of Control or the Eugenic Society would appoint some competent person to take up again the investigation of these same pedigrees; for he believed very much useful information might thus be acquired concerning the fate of mentally defective children during and after a great and prolonged war.

The question arose, Could certain of these mental deficiency cases be uplifted, and how were such cases to be selected? The closest investigation would be necessary. It did not suffice for the social worker to undertake this unaided. The efforts of the social worker must be correlated with those of the medical man, who would devote attention to the child and to the conditions which had given rise to the deficiency. He had been very much interested in the relation of syphilis to degeneracy. He had occasion to examine in one of the pedigrees taken for the purpose of this investigation a child who had died, and he found the spirochete of syphilis in every organ of the body. He had no doubt that a great many others would be found similarly affected. It was only by a close investigation on the medical as well as on the social side that this problem could be elucidated further.

Personally he was not disposed to think that sterilization was advisable—for this reason, that the people who were sterilized were not made in any respect better able to compete with their fellows. They would still want care and supervision just the same after sterilization as before. He agreed with what Dr. Campbell had said, that many of these persons could be made useful members of the community if taught properly to use their hands. A very important point emphasized by Dr. Campbell, with which the speaker thoroughly agreed, was the need for teaching in the medical schools a knowledge of human character. Some time ago the dean of the Manchester medical school wrote and asked him what he would advise with regard to the teaching of psychology, and he replied that he would advise a course of lectures on psychology applied to medicine at the end of the physiological course. After the war many men went into the practice of medicine utterly ignorant of the fundamental facts of human nature. He was sure that the airing of the whole subject at that Sectional meeting would do a great amount of good. Such facts as Dr. Campbell from the other side of the Atlantic had stated really went to the root of the matter.

# GENERAL DISCUSSION.

Miss Dyer Fox (Honorary Secretary, Central Association for Mental Welfare) said that there must be a very large proportion of defectives the greater part of whose lives would be passed, not in institutions, but in the free community, and these people must be protected and assisted because they especially would be subject to stress and strain. As early as possible in the life of the defective child it would be necessary for those concerned for his supervision to put to themselves the question, "Is this child going to be able to take a place in the community where he can compete with others in ordinary industrial life with some remanized production, or have we to train this child for

Dr. Joseph F. E. Parryaux (Mental and Neurological Inspector, Ministry of Pensions) put forward certain objections to the policy of sterilization which had been advocated by Dr. Gibbon. His first objection was that there would be enormous difficulties in deciding who was to be sterilized. The present difficulties in deciding who was to be segregated were great enough. Moreover, the only persons whom they could with any absolute certainty at the present time decide to be fit cases for sterilization were just those persons who would need segregation also on account of their antisocial tendencies. Further, if the figure for mental defectives in the population be taken as 3 or 4 per 1,000, it had been computed that on that basis some 10 per cent. of the population, who were carriers of mental defect, would have to be sterilized. Moreover, no really good result would be forthcoming until a very long period had elapsed. In the meantime, therefore, it was necessary to consider educational methods, and these must

life in an institution?" The standard test for entry into the special schools should not be, "Is this child capable of benefiting by education in a special school?" It would be a reflection upon any school to suggest that a child attending it could not receive benefit. It was true that there were children who were capable of receiving far greater benefits than others. But the special school was conducted on lines which should make it possible for the child to take its place afterwards in the community, and the admission of children must be regarded from this point of view. The simple measure of institutional accommodation would not go far towards solving this problem. Institutions and colonies were necessary for conduct cases, for low grades, for the unstable and erratic, but for the majority of defectives there must be a constructive and well-thought-out system of care whilst in the community. The question of suitable education and training for community life then became of paramount importance. The unfinished and ungraded he was unfit for even the simplest mechanical operations, and in the lower grades a still more helpless burden. In all such cases, along with the maximum of economic usefulness, there went—a fact too little realized—the maximum of mental strain on the family. If defectives came, as they frequently did, from families of bad stock, with members predisposed to instability and mental trouble, this was all the more reason why an uncontrolled and undisciplined defective should not be added to the family burden. Some experience of cases in all classes, rich and poor, had brought home to the speaker the waste of the efficient in the care of the absolutely inefficient. To meet the problem the first necessity was a reasonably uniform standard as to what was meant by children who required special training. At present the standard was variable, dependent more upon the point of view of the individual examiner than upon anything else. There should be some machinery for the discussion of such cases by groups—not confined to school medical officers, but including also general practitioners, teachers, and social workers. Through such groups a practical working rule might be evolved, so that at any rate they would learn the size and bearing of the problem they were tackling. Then it was necessary to arrive at a simple working knowledge of what training could mean and could do for the defective. The common sense of training the defective could be acquired even by people who never practiced it. Experts, both medical and educational, must be available to help in deciding what type of training a child required and what its future possibilities were. A certain standard capacity for taking a place in the community should entitle a child to a highly specialized form of teaching. Training must begin early in the home or school and might continue for many years, right into adult age. It must be continuous, and if the strain of life in the community was too great for the defective there must be some means of recalling him into a hostel or half-way house. A great deal of care was needed also in the provision of handicraft classes and suitable mechanical work for each case. The organization of suitable work for defectives ought to be undertaken expert-mentally as soon as labour conditions became normal.

some birds, spontaneous recovery from fibrillation frequently occurs, but in the higher mammals, and probably in man, the condition of true fibrillation seems to be invariably fatal—in the absence of the remedial measure of cardiac "massage," which may, in animals at least, be supplemented by the administration of certain drugs, while artificial respiration is maintained. Some instances of assumed spontaneous recovery in the higher mammals and in man are probably not cases where true fibrillation had been fully established, but a related though essentially different condition, which may easily be mistaken for true fibrillation.

The essential feature of fibrillation is the establishment of a mechanism of circulating excitation in the musculature, depending on a derangement of the normal relations of (1) the time taken for conduction of the excitation wave over the ventricular muscle, and (2) the refractory period of the individual fibres. If the conduction time is unduly prolonged, or the refractory period is relatively too short, re-excitation is apt to occur when the excitation wave reaches fibres that have already recovered sufficiently after the previous excitation to respond again; the excitation wave can then circulate through the complexly arranged intercommunicating fasciculi; after a time it becomes feeble and slower as exhaustion develops, until in a few minutes all visible movement becomes extinguished. If rhythmical compression (massage) of the ventricles is employed (while artificial respiration is kept up) the fibrillation may be maintained for prolonged periods (an hour or longer), with ultimate recovery under favourable conditions; and such a heart may show regular and vigorous action for the remainder of a long experiment extending over hours.

So long ago as 1887<sup>7</sup> I described this mechanism as a peristaltic contraction wave along the complexly arranged and intercommunicating muscular bundles, in contradistinction to the normal beat.

"The peristaltic contraction travelling along such a structure as the ventricular wall must reach adjacent muscle bundles at different points of time, and since these bundles are connected with one another by anastomosing branches, the contraction would naturally be propagated from one contracting fibre to another over which the contraction wave had already passed. Hence, if the fibres are sufficiently excitable and ready to respond to contraction waves reaching them, there would evidently be a more or less rapid series of contractions in each muscular bundle in consequence of the successive contraction waves reaching that bundle from different directions along its fibres of anastomosis with other bundles. Hence the movement would tend to go on until the excitability of the muscular tissue had been lowered so that it failed to respond with a rapid series of contractions. Then there might be some isolated peristaltic contractions, such as I have often seen after the cessation of the fibrillar movement."

These conclusions were confirmed and extended in a paper in 1918,<sup>8</sup> while in the interval similar views had been advanced and supported by experimental evidence—by Mines<sup>9</sup> (1913) in the case of the frog heart and by Garrey<sup>10</sup> (1914) in the mammalian heart. Suggestive experiments had been made by Mayer<sup>11</sup> (1908) on medusa, etc.

#### *Relations of Refractory Period and Conduction Time.*

If the fundamental importance of the relation between the duration of the refractory period and the conduction time of the muscle is kept in view it is easy to understand how the mechanism of circulating excitation may come into operation under very diverse conditions affecting the ventricles. Any influence cutting down the refractory period or lengthening the conduction time disproportionately must naturally tend to favour the process of re-excitation; a combination of such changes is, of course, still more effective. Hence the development of fibrillation is witnessed at one time as an apparently "spontaneous" event in a vigorous heart manifesting signs of extreme irritability (for example, from chloroform, digitalis, etc.) or in a normal heart subjected to stimulation—excessive rapidity of excitation playing an essential part by shortening the refractory period and slowing the conduction time. At another time fibrillation appears in a heart that presents features of grave depression, diminished contraction force, loss of tone, lessened excitability, and—what is the determining factor in this case—pronounced slowing of the propagation of the excitatory wave, relatively to the duration of the refractory period; such may be seen in poisoning by potassium salts, extreme cooling, etc.; thus it is often a terminal, or approximately terminal, phase in

the dying heart. In some depressed hearts there is a decided liability to fibrillation from mechanical disturbance, external pressure on the ventricles, incising the pericardium so as to remove its support from a relaxed ventricular wall, etc. In either case, whether fibrillation is a manifestation of perverted irritability or of abnormal depression, the same explanation of disturbed relationship between the processes named holds good.

In accordance with this conception it is readily intelligible that the *absolute* values of refractory period and conduction time may undergo extensive variation without fibrillation being set up; if both of these factors vary proportionately the conditions of circulating excitation do not arise. Thus artificial cooling of the heart, stopping short of a certain extreme point (about 23° C. in the perfused cat's heart), does not induce fibrillation, there being a concurrent lengthening of refractory period and conduction time as the cooling goes on—within the limit stated.

Conversely there may be, as results of a rise of temperature, etc., a marked shortening of the refractory period without fibrillation occurring, the rate of conduction of the excitatory impulse being also accelerated. The essential dependence of the mechanism of fibrillation on the factors named makes it clear why there should be no constant or necessary relation between the incidence of fibrillation, and even great alterations in contractile force, tone, etc. Dilatation of the ventricles is credited by Levy with a protective influence; this view is negated by various observed facts—among others the proneness to fibrillation seen in ventricles weakened, relaxed, and distended as a result of potassium poisoning; and conversely, the marked resistance or insusceptibility to fibrillation in ventricles that are of small volume, acting strongly and rapidly and well emptied at each beat, in sequence to a large dose of adrenaline, etc. So long as the essential relationship, described above, is not upset a heart may be profoundly influenced in many ways without fibrillating: it may beat very rapidly or very slowly, regularly or very irregularly, powerfully or feebly; it may be well emptied or imperfectly emptied at each beat—with consequent distension in the latter case; it may be very sensitive or very dull to direct stimulation, and its muscle may be lax or firm, etc.

#### *Pseudo-Fibrillation.*

Apart from the disastrous event of true fibrillation there is also to be observed under certain experimental conditions (for example, rapid artificial excitation by a series of electrical shocks, mechanical stimulation, etc.) a temporary condition in the ventricles presenting many points of resemblance to true fibrillation—a degree of inco-ordination or asynchronous contraction of the musculature, recognizable on inspection and on palpation of the ventricular substance, attended by great reduction in the range of contraction movement and very little expulsion of blood at each beat, a great fall in arterial pressure, and a failure of recognizable pulsation in the peripheral arteries, etc. It is impossible to distinguish this condition from true fibrillation by examination of the arterial pulse.

Usually this condition is soon recovered from when the artificial stimulation is discontinued, though it may persist for variable periods. It apparently differs essentially from true fibrillation in its dependence on a rapid series of excitatory impulses emanating from a stimulated area or "spontaneously" from one or more irritable foci, these impulses forcing a succession of ventricular beats at a rate incompatible with their normal characters; cessation of these excitatory impulses is speedily followed by a reversion to the more moderate rates that are compatible with the normal type of beat. The non-persistence of the abnormal condition is due to the fact that the mechanism of circulating excitation, characteristic of true fibrillation, has not been fully established. To this condition I have applied the term "pseudo-fibrillation." It is probable that most, if not all, the alleged instances of transient fibrillation in man where recovery occurred—apart from the application of cardiac massage—were examples of pseudo-fibrillation as recognized experimentally; this would account for the features observed in man during the brief attack, and for the subsequent recovery.

copies that slow silent process of nature which certainly was no longer acting in a beneficial direction. With regard to sterilization Dr. Pridemore had suggested as a reason why sterilization should not be thought of seriously that to-day 10 per cent. of the community would require to be sterilized. She did not think that was really a sound argument. If to-day we were preserving and purifying the race by sterilization or segregation of 10 per cent. of the community, what percentage of sterilized or segregated individuals would be required? If the disease was very general it would hence be very difficultly controlled. It is also very difficultly of the cure, involving the segregation of a large part of the community, or its suppression.

Dr. R. A. GIBBONS, in reply to questions, said that it was absolutely wrong to affirm that the sexual feeling was in any way affected by sterilization, but sterilization must not be confounded with asexualization, in which the reproductive organs were removed, when, of course, sexual feeling disappeared. Sterilization in the manner he advocated meant not the slightest difference in any way to the feeling of the individual. To a member of the audience who challenged the statement that the number of feeble-minded persons was on the increase, Dr. Gibbons could only give the number of notified insane persons in England and Wales, which on January 1st, 1922, showed an increase of 3,370 on the figure for January 1st, 1921, and this again showed an increase of 3,580 on the corresponding figure for 1920.

The President (Dr. H. B. Brackenbury) said that, according to the practice in the Section in former years, it now fell to his lot to sum up the discussion. He doubted whether such a task was at all possible; all that he could hope to do was to indicate one or two of the facts which the discussion had elicited. Mental deficiency was mixed up with other social problems, and it had been borne in upon their minds that there were very many cases of crime and incompetence and antisocial behaviour with which mental deficiency had nothing to do, and it was quite possible that they had tended in the past to overestimate mental deficiency as a causal factor in antisocial conduct. No doubt mental deficiency was at the back of all the social evils in some extent, but there were also many other causes upon which they should be concentrating, and, correspondingly, by antisociality. Some of them were so very feeble-minded that they were not capable even of so acting, while others were in such a favourable environment that their antisocial action was completely ruled out. Therefore, while antisocial behaviour had many other causes besides mental defect, a good deal of mental defect existed without antisocial behaviour.

[illegible][illegible]

by fat—from the point of division of the main stem to the point where the two main divisions decrease rapidly in size. Monckeberg<sup>20</sup> described two cases of sudden death associated with lesions of the Purkinje fibres. One was a diphtheria case, where no gross changes were found in the myocardium, but fatty changes were shown by staining with Scharlach R in the main stem, branches, and subdivisions; the myocardium was fat-free. In the other case (trephining of skull, etc.) there were more pronounced fatty changes in the bundle fibres than in the myocardium, though some of the Purkinje fibres seemed to have remained normal.

It need hardly be recalled that several observers have described certain abnormal features in electrical records from the heart as being indicative of defective conduction in the main branches, bundle block (Lewis and others), or in the intraventricular Purkinje network (arborization block)—bizarre ventricular complexes with notching or splintering of the deflections, prolongation of the duration of the Q R S group oscillations, inversion of the T wave, etc., in addition to a remarkably low altitude of the curves in arborization block. (Oppenheimer and Rothschild,<sup>21</sup> Carter,<sup>22</sup> Willis,<sup>23</sup> and others.)

#### *Exciting Causes of Ventricular Fibrillation.*

In the many observed cases where all the facts point to ventricular fibrillation as the immediate cause of sudden death the common association of muscular exertion or emotional excitement is notable. The ever-recurring reports of sudden deaths during or shortly after exertion, in persons who up to the fatal issue had been able to pursue their usual avocations, emphasize the importance of the conditions attendant on muscular effort—those involving an increased demand on the powers of the heart and more or less stress on the organ. This is brought about in various ways: by the augmentation of rate and force and irritability through the agency of the cardiac nerves (diminution or suspension of vagus control and excitation of the cardiac sympathetic augmentor fibres), increased arterial pressure presenting greater resistance to the pumping out of the ventricular contents, increased diastolic filling due to more rapid inflow from the venae cavae, etc. Similar changes attend emotional excitement, with the exception of the greatly increased venous return to the heart depending on the pumping action of the working muscles during exertion driving on the blood in the veins.

While the normal heart is not injured by such changes, and in virtue of its great reserve power easily responds to increased demands on it, a heart that is temporarily or permanently in an abnormal condition of excessive susceptibility is apt to be thrown into fibrillation.

#### *Susceptibility to Ventricular Fibrillation.*

Both in healthy and diseased animals notable differences in the ease with which fibrillation may be induced were seen under experimental conditions that were apparently similar. And a heart may sometimes be seen, under altered conditions, to pass from the susceptible condition to a stable one, which may be exceedingly resistant to the induction of fibrillation by various forms of stimulation that are usually very effective. Or a change in the opposite sense may take place; or there may be variation from one phase to another more than once in the course of a single experiment in the case of a healthy heart subjected to certain abnormal influences. On the other hand, there are many cases where the abnormal susceptibility is a persistent one associated with altered nutritive conditions, toxic agencies, etc., in the muscle.

In healthy animals, cats particularly, a great susceptibility to fibrillation may be established by the administration of chloroform; the relation of this condition to the phase of light chloroform anaesthesia has been specially worked out by Levy, most (though not the whole) of whose results are in agreement with those obtained by the present writer over a long series of years. It is after a deeper phase of chloroform anaesthesia that the lighter phase is apt to be attended by the marked susceptibility referred to.

In the latter condition fibrillation is often readily induced by stimulation of afferent nerves in various ways—resulting in reflex contraction of skeletal muscles, disturbance of

respiration, rise of blood pressure, increased rate and force of the heart with increased return of blood through the great veins, etc.—in short, the same group of changes that occur in muscular effort, and brought about in similar fashion through the instrumentality of the vagus and cardio augmentor nerves, excitation of the respiratory and vasomotor centres, and the mechanical action of the skeletal muscles in propelling blood more rapidly back to the heart by the veins—increasing the rate of its diastolic filling and its output and work per minute very largely.

It is plain that it is through these changes that the sudden fibrillation of the ventricles is determined in a susceptible heart under chloroform, and there is a strong *a priori* case for the presence of a similar mechanism in the occurrence of fibrillation and sudden death (apart from chloroform) during or shortly after muscular effort—granted a condition of abnormal susceptibility in the ventricular muscle.

In addition to chloroform there are various other toxic agencies capable of establishing the hypersensitive state. Referring to drugs, it is well known from experimental evidence (adduced by Cushny and others) that bodies of the digitalis series have a powerful influence in this direction—as also have barium salts, etc.—and when pushed to extremity kill by causing fibrillation. A whole series of chemical substances might be cited as having well defined effects in this direction. And some abnormal metabolic products may well exercise a similar influence in this respect on the cardiac muscle. The development of the hypersensitive condition is not necessarily attended by any recognizable structural alteration. A prominent part in the setting up of abnormal susceptibility to fibrillation must be assigned to defective coronary blood supply.

#### *Some Effects of Experimental Coronary Obstruction.*

It is unnecessary to recall in detail the long series of experimental investigations at the hands of many workers which have demonstrated the frequent occurrence of fibrillation as a result of ligation of a coronary artery or one of its larger branches. The evidence available leaves little, if any, room for doubt that death from sudden coronary obstruction in man is due to fibrillation; the clinical features of many recorded cases are very significant, taken in conjunction with the very definite facts established by experiment in animals. The reason of the difference between non-fatal and suddenly fatal coronary obstruction is usually to be found in the non-occurrence or occurrence of ventricular fibrillation in the different cases.

It has been found experimentally that coronary occlusion, if sufficient to prove fatal, may do so in more than one way: (1) it may kill rapidly (minutes) from acute ischaemia causing ventricular fibrillation, or (2) failing this, it leads to damaged nutrition with degenerative changes (anaemia necrosis, fibrosis, etc.); these changes, apart from leading in rare instances to rupture of the heart, naturally diminish the contractile efficiency in degrees varying according to the severity of the anaemia and its distribution. Recovery may occur and life be prolonged indefinitely; or death may be suddenly caused by the supervention of fibrillation. It is easy to understand how altered functional relations in the tissues of the damaged area may lend themselves under certain conditions to the decisive upset of the normal relations of refractory period and conduction time in the ventricular walls. It remains to be seen whether the tendency to fibrillation after coronary ligation is dependent mainly on the conditions induced in the Purkinje system or in the ordinary myocardium or in both of these.

The significance of some of these results of experimental physiology does not seem to have been fully realized in relation to their bearing on the human subject. In this connexion the convincing researches of W. T. Porter<sup>24</sup> (1896), Baumgarten<sup>25</sup> (1899), Miller and Matthews<sup>26</sup> (1909), and F. M. Smith<sup>27</sup> (1918) are specially relevant. Numerous observations show that in presence of the defective blood supply following ligation the abnormal conditions that develop in the anaemic areas can not only predispose and lead up—often after months—to fibrillation, either during muscular exertion or during rest, but that the abrupt onset of fatal fibrillation may come without preceding signs of cardiac failure, as tested by exercise, or without immediately premonitory evidences of cardiac disturbance in the shape of

all infection was over and where the heart already damaged might be trained to effort. Dr. Grey Combs (Bristol) differed from Dr. Lhmann as to the efficacy of salicylate in reducing the severity of cardiac rheumatism. The programme before any committee that would be set up might be divided into prevention, propaganda, and treatment of these prevention should come first. An examination of the conditions predisposing to infection should take a foremost place. Dr. W. Attlee (Edon) said that in public schools practically no acute rheumatism or chorea was seen, and so hearts crippled by rheumatism were very rare. But there were large numbers of functional hearts in which abnormal signs were found accidentally or in the course of routine examination, but which gave no symptoms. De-parture from the normal physical signs in the heart of a rapidly growing boy meant very little in the absence of symptoms. It was very doubtful if restriction of games in these cases was of any value, and it certainly did harm to the patient generally. Dr. Raven (Bristol) said that fresh air was very necessary for the rheumatic case, but the ordinary convalescent home was too noisy. In a rest home the question arose how long the child was to be kept to prevent recrudescence. Every child should stay six to eight months. He deprecated any routine rest, but was necessary because of infection in the heart muscle. Dr. Layton (Walsall) said that when patients were ordered by an out-patient physician at a hospital to go home to bed for a month, the general practitioner should be written to and asked to supervise the administration of salicylate. Dr. C. O. Hawthorne (London) emphasized the importance of prophylactic efforts, but did not approve of heavy propaganda to a special committee; it should be done through general practitioners. He submitted that the adult heart escaped rheumatic infection because the arthritic pain in the adult enforced rest, and that could not be done in the case of a child until the parents were aware of the danger which slight illness might entail. Dr. A. J. Thomson reviewed his experience in dealing with the problem at the Barberville Institution in Birmingham. The outstanding clinical difficulties were to determine when the infection giving rise to carditis had become quiescent, and to discover when a child had become free from the danger of reinfection. He described the methods he adopted to obtain an answer to these questions, but added that simple reliable tests had not yet been evolved. Dr. Moffet (Birmingham) as a school medical inspector said the type of case had very much altered in recent years. There was urgent need for more hospital beds. Sir Thomas Horder agreed with Dr. Raven about the significance of a diastolic murmur as a premortuary sign of mitral stenosis. Mitral stenosis differed in its evolution from mitral regurgitation; most cases of the latter resulted from acute rheumatic endocarditis, whereas most cases of mitral stenosis resulted from chronic inflammatory process, often afebrile—not a vegetative affair of the cusps, but a slow infiltration of the valve.

Dr. Langley (Manchester) remarked on the similarity between the course of tuberculous and rheumatism. Both improved on graduated exercises, but the response of effort to the streptococcus of rheumatism was not the same; one was easy of recognition and the other not. Dr. Routh (Southsea) commented on the great difficulty of tracing the origin of valvular defects in adults who had not known their had organic heart disease. The recuperative power of the child's heart was extraordinary. In private practice acute rheumatism was very rare, and the subacute and chronic cases were very difficult to deal with. Dr. Whittington (Hove) stressed Dr. Attlee's opinion that properly regulated exercises were much better than depriving schoolboys of games. Dr. Miller, in reply, thought the meeting was in general agreement as to the necessity of rest in the treatment of cardiac disease, but that too prolonged bed might be a drawback. He was glad they felt that the time had come for investigation.

*Friday, July 27th.*

At the final session the Section discussed the subject of chronic bronchitis, with Dr. G. A. Allan (Glasgow) in the chair. Dr. J. J. Perkins said that chronic bronchitis

was usually secondary to some chronic pre-existing disease, especially of the upper respiratory tract, the treatment of which was the essential factor for success. The health and activity of the lungs must be maintained by fresh air, exercise, and special respiratory exercises. Dr. J. O. Syme (Bristol) discussed the bacteriology and vaccine treatment. He took a very optimistic view and maintained that improvement was usual, cure frequent, and the patients were never made worse. Chronic bronchitis being due to a mixed infection, autogenous vaccine was desirable. The exciting organisms were constantly present in the nose, and details for the collection of material for bacteriological examination were given. The dose of vaccine must be sufficient to excite a reaction and treatment must be continued for at least three months. Dr. M. G. Foster (Harrowgate) maintained that in early cases climatic treatment enabled habits of coughing to be set aside. Dry air, lessened secretion, and diminished air pressure of the Alps might be of great value in the winter, but at high altitudes insomnia was often aggravated; the chest wall must not be rigid. Spa treatment was of value in early cases. When bronchitis was firmly established the aim was to diminish secretion. With hard cough and scanty expectoration, a moist atmosphere was advisable; asthma cases should be above sea level. Mr. G. Secombe Hett said that all cases which he as a throat surgeon saw were descending infections from the upper respiratory tract—in children a poor airway and infected tonsils were common predisposing causes of bronchitis. A deflected septum induced nasal catarrh, and served to infect and re-infect the bronchi. Tonsillar infection in adults was less likely to produce bronchitis than in children; infected teeth should always be removed. Removal of pus might relieve chronic bronchitis, and asthma by permitting drainage of infected ethmoidal cells. Dr. A. C. Inman had been disappointed with results of vaccine treatment. It was of the utmost importance to overhaul the patient thoroughly. Tubercle and syphilis should always be borne in mind in investigating the cause of chronic bronchitis. Cases from the bacteriological point of view might be divided into two classes: (1) Streptococcal, in which the results of vaccine treatment were invariably disappointing; and (2) Friedländer bacillus, the one type curable by vaccine. Prophylactic inoculation should be carried out during periods free from catarrh. Dr. Edgar Collis (Cardiff), in a written communication read in his absence, said that chronic bronchitis caused more deaths than any other disease, especially in later life. Predisposing causes were wintry weather and atmospheric pollution; a process and prevention should be attempted by clearing the atmosphere. Dr. Florence Storer (Bournemouth) spoke of atelectasis as a very common cause of bronchitis; it might give rise to no local signs and only be detected by an x-ray photograph.

Dr. Aston Key (Portsmouth) said that one of the great troubles was that the bronchial mucous membrane was incapable of complete repair; he asked for more light on this subject. He agreed that many cases arose from obstruction to the nose, and these always succumbed to bronchitis. Whether the nose was operated on or not. Dr. G. B. Batten (Dulwich), from thirty-seven years' experience as a general practitioner, said that the gradual wearing of chronic bronchitis was of more importance than vaccines or surgical procedure in the upper air passages. Dr. Hyla Greves (Bournemouth) drew attention to the fact that chronic bronchitis was a secondary affection and that often underlying it was a constitutional disease—namely, gout, alcoholism, arterio-sclerosis, heart disease, or peribronchial tuberculosis. In treatment it was of the utmost importance to cultivate gradually the resistance to cold. Sir Thomas Horder also emphasized the importance of associated constitutional conditions. Should all cases of bronchial catarrh be grouped as chronic bronchitis? All cases were not infective; in some the infective agent was dominant, in others it played but a minor part, and this explained the success of vaccine in one class and its failure in the other. Intermediate between

being is capable of being helped, if he is normal, and that all who fail in life should be studied to see how far they require help, and what kind of help is essential, alike in their own interest and that of the community. At the same time all social workers should understand that mental defect, being a definite clinical entity, not uncommon among social failures, should always be thought of first, and not last.

In work with criminals and delinquents the same spirit should prevail. Punishment cannot help those who require treatment or re-education. So many delinquents—at any rate so many of those who are caught by the police—do require such treatment that the public would welcome a thorough preliminary medical investigation to determine how far the offender is a deliberate wrong-doer, and how far a victim of his environment. Such ideas are sometimes not appreciated by the legal element, who think they alone are competent to deal with such cases, despite the unsatisfactory results they often obtain; they sometimes regard the medical psychologist as a dangerous and unbalanced crank, who wants to segregate every mental defective he can find, and to explain away or gloss over the wrong-doing of all other delinquents. But the judicial authorities must understand that the psychologist believes above everything in the gospel of hard work, and wants to help those who can be helped, with due regard to the safety of the community, and to segregate the impossible, as long as they remain impossible.

Again, take the problem of the unemployed, many of whom are said to be unemployable. One of the first steps should be to sort out the mentally defective; the dole never deals with their problem. It is an extravagant way of treating them, and leaves them free to reproduce other degenerates.

So too with war pensions and "shell shock" cases: some of these are, always have been, and always will be, mentally defective; the sooner those are weeded out the better for them, and the better for those who, both by their past record and their future possibilities, are entitled to skilled and expensive treatment.

In some of these groups will be found many borderland cases, who might be classified in other ways. When they are taken into account—for they cannot be ignored—and when there are recognized also the incipient, but as yet undeveloped, cases of adolescent insanity which are in many ways closely associated with mental defect, it becomes clear that the group which primarily or secondarily, owing to their mental condition, requires care is far from insignificant. Only one in every two hundred of the population may be a well marked mental defective, but the number of those who require a good deal of help, in part at least because of their psychological inferiority, is larger. Dr. Clarke of Toronto in his Maudsley lecture told us that out of 3,442 cases under 16 met with in their clinic 8 per cent. were classed as suffering from mental disease or psychopathic inferiority. Although it is possible to recognize in many such cases definite nutritional, endocrine, or other important failure, to class them in any other way than as psychopathic is only evading the issue. There is no reason for thinking that in our older country with its large cities, and correspondingly large slums, the psychologically inferior are less numerous.

In dealing with this problem we must adopt a broad outlook, and not attempt to pigeon-hole different varieties of one group, the essential feature of which is inability to adjust psychologically to their environment. If the number of the psychologically inferior seems to be greater than we had realized, it does not follow that we need be pessimistic. Once we recognize the group, study its development and deal with it, we can be optimistic. We must not be so blindly optimistic as to think we can eliminate the type. Defectives always have existed, and always will exist. It is not certain that there is a bigger percentage than there used to be. It may only be that the circumstances and conditions of our present civilization make them more obvious. The principal cause is heredity; therefore segregation, even if only partial, will reduce the number. But heredity, although the outstanding cause, is not the only cause. The statistics which

seemed at one time to lead almost inevitably to the conclusion that heredity was the only factor that mattered have been shown to have been unduly stressed. In some cases this was due to the fact that what was likely to be inherited was not mental defect, but a psychopathic make-up; in others, notably some of the American records, the figures were based not on scientific investigation, but on hearsay evidence obtained long after the unsatisfactory ancestor was dead. Clarence Darrow is responsible for saying that the alarmist record of the so-called Kallikak family was partly obtained in this way, and therefore is not necessarily correct. This we can easily believe, because we know that a satisfactory member of society is not always followed by equally satisfactory descendants; while the progeny of the less desirable sometimes reverts to the normal. This does not belittle the importance of heredity and segregation of the defective, but will remind you that segregation alone will not solve the problem; in addition all unfavourable factors must be eliminated as far as possible. If both these principles receive attention a degree of success well worth attaining will be achieved. Those who have the care of the mentally defective and all other social workers must join hands to combat the racial poisons, syphilis and alcohol. Other known unfavourable agencies must not be forgotten, such as infectious disease of the mother during pregnancy. Toxins and bad environment must contribute in some cases to the incidence of mental defect. It has been established that at the time when the determiners separate out of the germ cells, healthy influences promote variation of a good type, while unfavourable ones tend towards a bad type.

Once mental defect is established little can be done to eradicate it. The great opportunity is at the ante-natal clinic, where disease must be dealt with, and failure of endocrine and other organs receive attention. But it is only those who come very early to that clinic who can expect much help. Highly skilled medical practitioners are essential there; in addition a high standard of national health, especially among married women, must be achieved. Once a child is born defective the opportunity has usually gone. But even then much may be done by careful home training in the early years to develop a capacity for some service to the community, and to diminish the potentiality for harm. It is in the school clinic that the opportunity occurs for recognizing and scheduling the pathological or asocial child. All such require careful supervision, not with the object, as some cranks think, of shutting them up for life the first time they fail ever so little, but in the hope of preventing failure, and of training and building up character so that they may contribute something, in however humble a capacity, to the work of the world. The more efficient the supervision, the more thorough the early investigation, the fewer will have to be segregated later. The public must be taught that those who are segregated are being treated and not punished; that it is the only way in which they can lead happy and useful lives. The institutional life essential for them is arranged not only for their benefit, but also in the interests of their normal brothers and sisters, who are often seriously handicapped by the presence of a defective in the home or the school.

You will see that I attach great importance both to the ante-natal clinic and the school clinic, which should deal not only with the physical make-up but also with the psychological make-up of every child. Their medical officers should have knowledge and experience, and not be merely recently qualified practitioners taking up the work as a stop-gap. We require larger vision in such matters, such vision as will prevent our grudging the necessary expenditure at the only times when expenditure can do much good. We want the vision, also, which will enable us to see that all social workers are working for the same end, and must pull together. So, too, we must not cavil over which authority cares for the feeble-minded. What does it matter whether it is the Guardians, the Mental Deficiency Committee, or the Education Authority which acts, provided care is given, the defective helped, and the community protected?

At the present moment many local authorities are forced

Mr. Dickinson Berry strongly advocated in givine cases the combination of anaesthetics with light general anaesthesia by ether. Mr. Basil Hall (Bradford) had had the good fortune of doing practically all his work with one anaesthetic, upon whom he depended and to whom he attributed in great measure his success. He deprecated the multiplication of apparatus by anaesthetists. He regarded ether as the most satisfactory anaesthetic for general use, preceded by hypodermic injection of heroin or morphine, or by a few whiffs of chloroform for induction. Sir Crip English spoke in favour of ethanaseal and of the employment of ethyl chloride for induction. The discussion was also taken part in by Dr. A. L. Flemming (Bristol), Mr. A. A. McConnell (Dublin), Mr. Cuthbert (Gloucester), and Mr. Farnett (London), and the results of the debate were summed up by Mr. Trotter. Mr. A. Clifford Johnson (London) concluded the work of the Section by reading a paper on the division of the vas deferens in prostatectomy. Sir Henry M. W. Gray conveyed the thanks of the Section to the secretaries, Messrs. B. C. Maybury and Harold Burrows, for the success of its meetings. Thanks to the President were accorded on the motion of Mr. Burgess, who expressed the hope that Sir Henry Gray would achieve success and happiness in his work in Canada.

## SECTION OF OBSTETRICS AND GYNAECOLOGY.

Thursday, July 26th.

and abuse of forceps. There was a very crowded attendance. In calling upon Mr. Comyns Berkeley, the President asked everyone present who had any experience of forceps to state his views. In the opening paper Mr. Comyns Berkeley expressed the opinion that the unsatisfactory position of the forceps operation to-day was due to inefficient teaching. The blame rested more upon the shoulders of the teachers than on the family doctor. But while the teachers must bear their full share, they were not entirely at fault, as the proper teaching of midwifery even now was not insisted upon by most of the examining bodies, while inadequate facilities for the proper teaching of the subject had not yet been provided. The number of cases was insufficient and there were not enough obstetric beds in either the general or the lying-in hospitals. Yet the importance of proper teaching could not be overestimated, for it is in it that a man would often experience difficulty in determining whether a particular case was normal or otherwise. The true conduct of forceps was abnormal in itself. There were occasions when the forceps had to be used, but the less frequently they were employed the better. The only way to bring about such a reduction was by efficient ante-natal supervision. The unsatisfactory position of the forceps operation was easily prevented, but the use of forceps would usually preserve a husband and wife from the pain which the ordinary surgical operation in the cases of the obstetric emergencies would be expected by the patient to be able to carry out all unnecessary measures during the last day. This is possible—nothing is impossible—by the use of the uterus without the potential risk of infecting it. It was not an unfair view of the potential trouble over the use of the forceps so-called for the reason that the local authorities should be responsible for providing the proper aids to childbirth. His experience had led him to the conclusion that the forceps was paid for by students for the mechanism of labour rather than by any other subject in midwifery. The operation of forceps extraction must always interfere with the normal mechanism, and in some cases was so disastrous. It is that the forceps were often misused which was due to the fact that a large number of students

The preceding opened with a paper by Mr. Beckwith Whitehouse and Dr. Henry Featherstone upon certain observations on the innervation of the uterus. Their interest in the problem had been stimulated by the observation of the extraordinary power of contraction possessed by the uterus in cases of Caesarean section performed under lumbar spinal anaesthesia with tropacocaine. They had made observations upon the uterus at all stages of pregnancy under spinal anaesthesia, but they did not desire their deductions yet to be considered in any way final; they might require modification as the work proceeded. The nervous mechanism controlling the uterus was constituted by three systems—local, sympathetic, lumbosacral and nomic. The "local" mechanism was capable of producing rhythmic uterine contractions and was independent of either involuntary muscle. The sympathetic stimuli were motor to the circular muscle fibres and inhibitory to the longitudinal fibres and inhibitory to the circular motor to the longitudinal bundles. The lumbar cord stimuli were motor to the longitudinal fibres and inhibitory to the circular fibres. In regard to the practical application of these results, the advantages of lumbar anaesthesia, either alone or combined with general anaesthesia, in classical Caesarean section were very evident in securing a firm contraction of the uterus and reduction of haemorrhage to a negligible amount. In cases where the uterus was exhausted, spinal anaesthesia should certainly diminish the tendency to post-anaesthetic haemorrhage. For the same reason, spinal anaesthesia was to be preferred when it was necessary to evacuate the uterus by the vaginal route in the earlier stages of labour.

Friday, July 27th.

The large attendance at the meeting of the Section of Obstetrics and Gynaecology, which was held in the afternoon at 2.30, was given by Lieut.-Colonel Andrew Buchanan, I.M.S.

Dr. Douglas (Cupar), Dr. Evans (Buckingham), Dr. Gerald Giffard, I.M.S., and the President took part. Mr. Grove, Dr. Buchanan (Glasgow), Dr. Lewis (Southport), Dr. Campbell (Belfast), Professor Johnstone (Belfast), Dr. Rivett (London), Dr. McKisickie, Colonel Buchanan, Mr. Hendry (Glasgow), Dr. Forde (Portsmouth), and Mr. Hendry (Glasgow). A very lively discussion followed, in which Dr. Hendry was the chief exponent of the natural use of forceps. A very lively discussion followed, in which Dr. Hendry was the chief exponent of the natural use of forceps. A very lively discussion followed, in which Dr. Hendry was the chief exponent of the natural use of forceps.

criminals, while the Ministry of Health, through the Poor Law, deals with very large numbers and all types and ages of the mentally defective. These central authorities have corresponding local authorities, and although the Mental Deficiency Act created an elaborate system whereby a defective could be transferred from the care of one authority to that of another, it is found in practice that it is most difficult to secure complete co-operation between the various local authorities and that the procedure is far too complicated. It is still to a large extent true that "mentally defective persons pass from one authority or institution to another, helped or detained a little in each, but permanently cared for by none."

The fundamental idea of continuity of control was the prevention of personal degradation and disaster to the individual defective and of the attendant social evils. It was seen that by early recognition and protection defectives could receive sufficient training and care to prevent them becoming drunkards, criminals, "in and out" paupers, and the parents of children whom they could not support and whom they often neglect and ill treat. But the provisions of the Mental Deficiency Act, except in one instance, are insufficient to carry out this idea. Section 2, which sets out the classes of defectives "subject to be dealt with," shows that only those are eligible for care and protection in whose case some personal disaster has already taken place—for example, neglected, abandoned, or cruelly treated, found guilty of any criminal offence, undergoing imprisonment, habitual drunkard, in receipt of Poor Law relief when pregnant or at the time of giving birth to an illegitimate child, etc. The single exception is Section 2 (b), v, which gives the local education authorities power to notify to the committees for the care of defectives those children who would benefit by institution care or guardianship. This is the one provision of the Act which seems to have been framed with the idea of preventing disaster and securing continuity of care for those who need it, and if thoroughly carried into effect it would go far towards solving the whole problem.

Immediately after the passing of the Mental Deficiency Act the Elementary Education (Epileptic and Defective Children) Act was amended and its adoption by local education authorities made compulsory, and it would not be too much to say that the success of the former depends greatly on the thoroughness and efficiency with which the latter is administered. The early recognition through the local education authorities of all defective children, and their appropriate treatment, constitutes a first line of defence for the individual and the community. If defective children are scientifically studied and carefully trained, it is found possible to distinguish those who will need further care and protection from those who will benefit sufficiently by special training to become self-standing and able to manage themselves and their affairs.

Unfortunately the war and the consequent financial restrictions have prevented the Elementary Education (Epileptic and Defective Children) Act from being brought into complete operation. The last available figures in the annual report of the chief medical officer of the Board of Education show that some 16,000 mentally defective children are being dealt with in special schools out of an ascertained number of 31,000. The statistics of the After-care Committee which has been the longest time at work (twenty years), and has followed up 2,600 cases, show that only 28 per cent. of children who pass through special schools become self-supporting, and that all the others need some measure of support and protection and care.

It will be observed that the other 15,000 mentally defective children for whom no special schools have been provided will drift out from ordinary elementary schools into the general population without being notified under the Mental Deficiency Act, and are therefore, however much in need of care, not "subject to be dealt with" until some disaster brings them within its provisions. The restrictions on public expenditure seem likely to prevent any increase of the number of children admitted to special schools, and as the local education authorities do not notify feeble-minded children leaving ordinary elementary schools, numbers of defectives will leave at 14 without a chance of further help and care.

It is clear, therefore, that the chief means of making the Mental Deficiency Act really effective in the prevention of degradation and disaster to the feeble-minded, and expense to the community, is the thorough and scientific working of the Elementary Education (Epileptic and Defective Children) Act. If for financial reasons the work of this Act has to be curtailed, it is highly desirable that some temporary arrangement should be made whereby defective children needing control between the ages of 7 and 16 could be brought under the protection of the Mental Deficiency Act and properly supervised. Co-operation between the school medical officer and the medical officers of the statutory committees for the care of defectives might do much towards continuous care, but in order to secure full protection it should be the ordinary practice of the local education authority to report to the local authority any defective child leaving or excluded from an elementary school.

The next effort to obtain continuity of care by the provisions of the Mental Deficiency Act occurs in relation to cases who are constantly drifting in and out of Poor Law institutions. Section 30, Proviso ii, provides a means whereby a defective who needs continuous care may be transferred to the local authority and sent to a suitable institution. But the procedure set up has proved complicated and lengthy. It involves correspondence between two central and two local bodies, and it has, moreover, an element of uncertainty which discourages Poor Law guardians from putting it into effect. The local authority is sometimes unable, through want of accommodation, and sometimes unwilling, to assume responsibility, and it is not infrequently found that before all the formalities are completed defectives whom it is desired to protect have taken their discharge from the Poor Law institution. As an illustration of the great need for a better link between the two local bodies concerned, the following quotations are given from *A Review of the Conditions of Defectives in Poor Law Institutions*, which was published by the Board of Control in 1919.

"In twelve workhouses in one part of England forty-two mentally defective women were noted as cases in urgent need of control—twenty-three of these have had between them at least fifty-one children, two being pregnant at the time of the report; nineteen had not at present had children."

At another time the Commissioners say:

"One woman was reported to us as having had nine illegitimate children, six of whom were born in the house. We noted three cases of girls only 17 years of age with illegitimate children. One of these was pregnant for the second time, and one was certainly a certifiable imbecile, so defective that she could not wash and dress her baby. The powers of the Poor Law authorities have hitherto proved entirely insufficient for the protection of these mentally defective women. The treatment extended to them has been spasmodic and not continuous. It does not prevent them from becoming morally and physically degenerate, neither can it always secure the adequate and continuous care of their children."

Instances of the above description might be given from a very large number of Poor Law institutions, and, combined with the knowledge that numerous defectives come in touch with the Poor Law at an early period in their lives, show the desirability of trying at this stage to secure continuity of care and control. Even without further legislation much might be effected by the complete co-operation of the medical officer of the Statutory Committee for the Care of Defectives with the medical officer of the Poor Law institution. A routine procedure could be established whereby the local authority should always be informed when defectives leave a Poor Law institution; they could then be kept under supervision in order that help might be forthcoming if necessary. But to secure real continuity of care the transference of responsibility to the local authority should be made as simple as possible.

It is important to remember that the administrative difficulties referred to are such as must necessarily follow the initial stages of carrying out the provisions of the Mental Deficiency Act, and that the public owe a debt of gratitude to a large number of boards of guardians for consenting to receive mentally defective cases from local authorities.

The idea of continuity of care may be traced again in Section 16, which provides for transferring a defective who has recovered from an attack of insanity from a mental hospital to an institution for defectives. Very little use

had been noted in three cases, in one with gitter. The progressive, Addison's was also a common sequel, and pain in the limbs not uncommon. Dr. Hinds Howell (London) discussed the results which had followed in 34 cases under his own observation. Of these 6 died and 11 recovered completely. Nine had residual symptoms. Three cases of the Parkinsonian syndrome had made good recoveries, but others were progressive. The commonest symptoms were alterations in personality, especially a loss of emotional response. Such mental changes showed little tendency to improve. Of ocular defects the commonest sequel was a loss of power of convergence and accommodation. He went on to discuss the disorders of sleep, the curious disorders of respiration, and certain interesting relapsing cases. Dr. Freiling (London) confined his remarks to the ocular palsies as a sequel to the Parkinsonian syndrome. He quoted a case showing the strong resemblance of cases with residual ocular palsies to myasthenia gravis, and went on to contrast the features of the post-encephalitic Parkinsonian syndrome with the ordinary form of paralytic agitans. He concluded by emphasising the serious prognosis in these cases, many reports of 14 cases of Parkinsonism following epidemic encephalitis in which careful histological examinations had been made. In all of these changes in the substantia nigra in the mid-brain had been found. He discussed the calcification of the blood vessels, which he had found in the form of globules, chiefly in the anterior parts of the globus pallidus. His remarks were illustrated by a series of excellent lantern slides.

Dr. Symonds (London) remarked that in dealing with the sequelae the diagnosis must often be made in retrospect. The importance of amblyopic cases was discussed and two interesting cases quoted. The possible latent interval between the acute phase and the occurrence of any sequelae was a very important practical point, and it might extend to three years. He had been especially interested in the sensory disturbances of the disease, especially those of visceral sensibility, and thought that they might perhaps account for some of the curious attacks of respiratory and other disorders which occurred. Dr. McBride (London) raised the question as to whether most of the so-called sequelae were not really a persistence of the disease. Dr. Devine (Portsmouth), President of the Section, thought that perhaps some cases had been overlooked by psychiatrists, especially the amblyopic ones. The correlation between mental disorders and physical changes found in this disease might be called an epoch-making discovery.

Dr. Macleod Campbell (Boston) also mentioned the real practical importance of the latent interval, and discussed whether some of the sequelae were really recrudescences or mere residuum. He agreed that many amblyopic cases could be overlooked. There was a wide field for investigations into the psychology of these cases, especially in the different reactions shown by adults and children. Drs. Morris, Potts, Charneck Smith, and Hardcastle also spoke, and Dr. Buzzard briefly replied.

In the afternoon Dr. De Bono gave an admirable demonstration of the microscopic changes occurring in epidemic encephalitis and in the herptic encephalitis of experimental rabbits. A series of beautiful preparations were exhibited, and studied with the greatest interest by those present. Dr. McAlpine also showed specimens illustrating the changes in the basal ganglia and the calcification of blood vessels in human epidemic encephalitis. A most successful day's proceedings were concluded by a demonstration by Mr. Imman at the Eye and Ear Hospital of cases of squint and left-handedness in nervous children.

Friday, July 27th.

The proceedings at the closing session took the form of a discussion on the prognosis of psychoses occurring during adolescence. The chair was taken by Dr. Riddoch, Vice-President. A very good discussion was held, introduced by a paper full of interest and practical value, which was much appreciated. Dr. D. K. Henderson (Glasgow), after touching on the magnitude of the subject, went on to say how important it was that all connected with the training

of the young—parents, teachers, and doctors alike—should realize what a critical period that of adolescence was. Early changes in behaviour and character should be carefully noted, as they might indicate the beginning of a serious mental breakdown. Cases could be classified on the basis of organic visceral disease or on the broader biological conceptions of adaptation and adjustment. Dr. Appleton's well known differentiation by symptoms with dementia praecox had been useful, but he thought such a basis was unsafe, and one which tended to retard treatment and induce an unnecessarily pessimistic outlook. Attempts to regard and treat such cases from the organic or toxic side had, it was true, met with a certain measure of success, but many cases were quite unclouded by such methods. He believed that a wider conception was necessary, and the symptoms of the illness must be brought into line with the whole personality of the patient. In every case, therefore, the question would be asked, How has this patient failed to adapt himself, and what shape have his or her reactions taken? Details of cases were then given, illustrating forcibly and graphically the author's meaning.

Sir Frederick Mott said that though his own attention had been mainly fixed on the pathological side, he was much interested in the psychogenic factors, especially in their relation to the endocrine systems. He emphasized strongly the factor of genetic inadequacy as a predisposing factor of insanity. Each case was a biological problem of its own, and too much classification was a mistake. He discussed briefly his own work on the changes in the reproductive organs in dementia praecox, especially in regard to nuclear degenerations. Dr. Stokes (Portsmouth) discussed the question of the recovery rate in the dementia praecox type of case, and recalled the fact that Clouston had 15 per cent. of recoveries in five and a half years' work. The figures he gave showed a higher recovery rate among the manic-depressive type than in the dementia praecox type. Dr. Devine, President of the Section, said that the most important thing was the study of the reaction type of the soil in which the psychosis appeared. If it was a "shut in" type a deteriorating psychosis was probably present. The greater the exogenous stresses present in any case the well exemplified during the war. He quoted two very interesting cases, and concluded by pointing out the value of finding the right environment for the patient. Dr. Symonds (London) said that behaviour reactions were the most important study. Cases failed to come under care in the early stages, a fact which was probably due to the inadequate opportunities of training afforded to the medical student. He was strongly in favour of establishing in every large general hospital a mental ward which could be used for observation and treatment. Economic factors unfortunately interfered, and prevented endeavours to place cases in really suitable environments. Dr. Jackson (Portsmouth) asked for more guidance in treatment, especially as regards occupational training, in which he was a great believer. Dr. Stone (Northampton) spoke of the question from the point of view of the general practitioner. Dr. Marthew referred to the occupational treatment for mental cases in a general hospital. He also emphasized the importance of a study of the reaction types of the individuals. Dr. Henderson replied, and further interested the meeting by an account of the occupational treatment and training as practised in his own institution.

Friday, July 27th.

THE SECTION OF OPHTHALMOLOGY.

The President, Sir John Parsons, said the subject, "Ophthalmology in its relation to the Navy, Army, or Air Force," was in many of its aspects new, in none it was unimportant. Air Commodore David Munro, in his opening paper, said that "eye" determined success in games as in

local authority, either through its own officers or through a local voluntary association, to organize a guardianship scheme somewhat on the lines of the Brighton Guardianship Association. The essential features would be a wise choice of homes, of suitable cases, and of trained visitors who would keep in close touch with the defectives and report on their progress, mental and physical condition, and on any change in their surroundings or behaviour which might indicate the advisability of a transfer to an institution. Transfer from guardianship to a certified institution is a simple matter and can be effected under Section 7 by a variation of the order.

The provision of institutional accommodation is at once the most onerous and most valuable of the duties imposed on local authorities by the Act, and it is, unfortunately, one which it is impossible for the present to carry out efficiently owing to the severe financial restrictions consequent on the war. Even if full use is made of less expensive forms of care and treatment, such as supervision and guardianship, there will always remain large numbers of defectives whose condition calls urgently for institutional treatment, both in their own interests and in the interests of the community.

The existing accommodation for defectives at the present time is about 19,200 beds, and shows an increase of about 16,000 since the passing of the Mental Deficiency Act. But nearly 7,000 of these beds are in Poor Law institutions, and therefore do not represent the actual number available. Many of these places have already been filled up by ordinary paupers, while some of the Poor Law institutions limit the defectives they will receive to those belonging to their own union, with the result that, even if vacancies exist, they cannot be filled.

It must also be remembered that Poor Law institutions are, with a few exceptions, only approved for adults, and are only suitable for a certain limited class of defectives. They can seldom provide sufficient training and employment, and life in them for long periods is exceedingly confined and monotonous. A large proportion of this accommodation, therefore, can only be regarded as a temporary provision pending the establishment of suitable colonies. When we turn to the ordinary certified institutions, we find that vacancies are very difficult to obtain, and that most of the institutions have a long waiting list. The accommodation therein available on January 1st, 1923, was for 11,232 cases, and there were resident at that date 7,891, dealt with under the Mental Deficiency Act, and 2,126 other cases—totalling 10,017 in all, thus leaving only 1,215 vacancies. These are nearly all confined to one or two large and recently opened institutions, and are, generally speaking, only available for cases from the surrounding district. Only fourteen of the existing 126 local authorities have institutions of their own; the others are dependent on charitable and philanthropic efforts or on Poor Law institutions. No new institutions have been opened by local authorities during 1922. The number of mentally defective cases in institutions on January 1st, 1923, was 15,327.

In the foregoing pages an attempt has been made to show how far the Mental Deficiency Act has met the difficulties experienced by the community in adequately protecting the mentally defective. Twenty-five thousand cases have been ascertained, and 9,854 of them placed under supervision. Some 16,000 beds have been provided for those needing institutional care. Compared with the numbers needing protection, these figures cannot be said to constitute more than a beginning. There is no doubt that a much greater advance would have been made if it had not been for the war and the consequent financial restrictions. How long these restrictions will continue and what will be the future rate of advance it is impossible to foretell, but taking into consideration the high cost of building and of maintenance it may safely be assumed that progress will be very slow. This being so, thoughtful people are more and more inclined to consider whether there is any possibility of action on other and different lines.

Is there any method of community control outside institutions which would ensure the safety of the defective and the protection of the interests of the community?

How far is complete segregation of large numbers and varying types practicable, and if rigorously carried out how far would it cut off the supply?

If the community decides that the segregation of defectives is essential for its welfare, what steps can be taken to render it less irksome for the individual?

Is it possible to promote scientific research which may reveal the causes of congenital mental deficiency and suggest its prevention?

The answers to these questions will require many years of patient, untiring experimental work—the humane and scientific treatment of the mentally defective is yet in its infancy—but enough has been done to show that in the solution of this problem lies a hope for the gradual improvement of social conditions. Something has already been accomplished, and if the two Acts now in existence were brought into complete operation and thoroughly administered it would lead to an immediate reduction in drunkenness, pauperism, crime, illegitimate births, and venereal disease.

HENRY DEVINE, O.B.E., M.D., F.R.C.P.,

Medical Superintendent, Corporation Mental Hospital, Portsmouth.

#### SEGREGATION OF MENTAL DEFECTIVES.

WE all realize how difficult it is to deal effectively with the problem created by the presence of so many mental defectives in the community. In some respects segregation seems to be the most practical method of attacking the problem. It is not merely custody or imprisonment, but a method of treatment; it protects the community from what may be and often is a socially harmful person; and it effectually prevents propagation. At the same time segregation presents both sentimental and practical difficulties, and more especially so in those cases where it is perhaps most desirable from a social point of view. We feel no hesitation in recommending institution care in the case of low-grade defectives. We know that it is best for the child to be under skilled care—best for the parents in the long run, and certainly best for other members of the family group. Apart from the fact, however, that these cases are unproductive and an expense to the community, they do not constitute a very serious social problem, as they are harmless and unlikely to propagate. It is the high-grade cases which give rise to a social problem, and we may limit our discussion to these.

As mental deficiency has here to be considered in its social aspects there is no need to discuss segregation as a form of treatment—that is, from the individual point of view. The sociological reasons for placing the feeble-minded in institutions may be included under two headings: (1) The prevention of delinquency, vagrancy, prostitution, etc.; (2) the prevention of propagation by persons who will probably produce inferior children.

Dr. Potts, in his opening address, showed the relationship between mental deficiency and venereal disease, chronic drunkenness, illegitimacy, delinquency, and unemployment. There is, of course, not the least doubt that many defectives are a misery to themselves and a menace to others, and, this being so, it is both humane and socially necessary that they should be segregated in colonies or elsewhere. If such steps are taken, not only will these individuals cease to be destructive social units, but they will probably become useful members of the community in which they are placed, and almost self-supporting. In thus advocating segregation for certain defectives there is no suggestion of "attempting to rake as many as possible into the mentally defective institution net," as Dr. Potts aptly puts it. I do not think there is likely to be any abuse of segregation in this country. Apart from the practical difficulties involved in the segregation of all mental defectives, we all feel a profound aversion to depriving an individual of his liberty unless it is clearly necessary. In practice magistrates and medical men devote the most careful attention to the difficult high-grade cases, and only commit them to institutions after every other possibility has been explored. I do not think it necessary to add anything more as to the value of segregation as an instrument in the prevention of delinquency by irresponsible persons. Both Mrs. Pinsent and Dr. Potts have spoken so clearly, temperately, and humanely on this aspect of the question that I feel it unnecessary to expand

cases or groups of cases were extraordinarily variable, and the morphological characters of the same bacillus were observed to undergo considerable variations. It was evident that no one particular organism was the cause of summer diarrhoea; in fact he had come to the conclusion that the disease was not infective in the strict sense of the word. The primary cause was not bacteriological, but nutritional or metabolic. Resistance was lowered by such causes as improper feeding and prolonged exposure to heat, which led to secondary infection by bacteria. He hoped that in time fare centres were educating mothers in the proper clothing and feeding of their children. The use of dried milk and the reduction in the number of flies had eliminated important sources of infection.

The President, Dr. Cantley, could not agree that summer diarrhoea was not an infective disease. In his hospital infantile diarrhoea was nursed in the same way as typhoid, and yet cases of infection occasionally occurred in a ward; he was inclined to attribute this to flies. Some of the worst diarrhoeic cases began in well nourished children; in them a predisposing state of nutrition appeared to have nothing to do with it. He considered the disease infective, but many different organisms were involved. Dr. D. H. Patterson said that true "summer diarrhoea" occurred in only a small proportion of children who suffered from diarrhoea in summer. In his series of cases at Great Ormond Street there had been a history of unsatisfactory feeding in 50 per cent; the other half were in an extraordinarily good state of nutrition—they were in fact overfed. In no weather these children might easily get an acute intestinal upshot. If treated by being taken off all food, they passed rapidly into a state of acidosis, and acute fatty degeneration of the liver would be found at necropsy. Fermentation in the intestine was one of the chief causes of diarrhoea; the proof of this was that the most successful treatment was a diet in which fermentation was reduced to a minimum. Dr. Bernard Myers (London) had been astonished to find so many cases of summer diarrhoea in which nothing pathological was found at necropsy. He thought Finkelstein's classification more helpful than any other. A diet with too much carbohydrate and fat appeared to be specially prone to produce the disease; protein was usually well tolerated. Some cases, he thought, were due to nutritional disorder, and some infective; treatment varied according to the cause. Dr. Catherine Chisholm (Manchester) confirmed the value of Finkelstein's work in treating the decline in the disease was due to welfare centres and the care taken in cities to prevent sources of infection. Dr. Baumann (Johannesburg) said that in the past a mistake had been made in considering all cases as of infective rather than of nutritional origin. But it would not do to go to the other extreme. Both types were seen, Finkelstein seldom started his cases, and never for more than six hours; he gave buttermilk, which was a food rich in water and proteolytic decomposition they were alkaline, in fermentable lactose with lactic acid bacilli; he preferred a coarse method of introducing lactic acid bacilli; he preferred High irrigation of the colon was also useful. In acid fermentation the indications were the reverse; protein administration was more scientific and successful. Indiscriminate use of protein milk or sugar solutions was unsatisfactory. Dr. Nabarro and Dr. Patterson replied.

Dr. H. T. Ashby (Manchester) read a paper on the results of abdominal tuberculosis in children, based on the study of 250 cases. He insisted on the difficulty of diagnosis and the care needed to exclude cases of rickets or dyspepsia which might resemble tuberculous. He thought the human source of infection was commoner than the bovine. As to prognosis, if a case remained free of symptoms for two years

the outlook was good; under one year the cases were almost invariably fatal, but the prognosis improved as the child grew older. Most recoveries were complete. In some cases a mass of calcified glands could be felt many years later in the same situation as the former enlarged glands, but these old glands seemed to cause no trouble. Dr. E. A. Cockayne (London) agreed with Dr. Ashby on the absence of after-effects; calcified nodules and glands in the omentum produced no symptoms. Dr. Eric Pritchard did not regard abdominal tuberculosis under one year of age as necessarily fatal. For early diagnosis he injected old tuberculin; if the child was infected there was a local and focal reaction; on clinical evidence alone it was very difficult to say whether tuberculosis was present or not. Treatment by tuberculin had been very successful. Dr. Sweet said that most cases of abdominal tubercle in New Zealand were bovine. He had obtained very good results from treatment by tuberculin. Dr. Moynaux read a paper on radium for tuberculous cervical adenitis. The treatment was painless and safe provided the technique was carefully carried out, and he obtained apparent cure whenever it was properly followed. Cascating masses of glands, suppuration, and secondary infection and old sinuses were no contraindication to the method.

#### SECTION OF LARYNGOLOGY AND OTOTOLOGY.

Friday, July 27th.

In opening the discussion on spasms of the larynx, Sir Stclair Thomson (London), after a definition of terms, briefly reviewed the anatomy and physiology of the parts concerned and began by classifying the known causes of spasm. He emphasized throughout the importance of the psychological factor in intensifying and even originating spasm, and mentioned that in his long experience he had not had occasion to perform tracheotomy, though he was heart far from condemning the procedure where the strain on the heart was obviously too great. He was convinced that whooping-cough in adults sometimes was the cause of spasm [an original observation, this], and quoted cases due to gout, morphine habit, and tabes. Like most of his hearers he had found difficulty on occasion in distinguishing between abdominal paralysis and adductor spasm, but was able to indicate clinical methods of solving the problem. Having touched upon Semor's law, and spasms in anaesthesia, laryngismus stridulus, hiccup, and epilepsy, he concluded by summing up the lines of treatment at our disposal. The problem, as ever, depended upon diagnosis, and in each case a most exhaustive examination was necessary to ensure that we were not treating a case of paresis by sedative methods. Sir James Dundas-Grant drew a definite distinction between laryngismus stridulus and laryngitis stridulosa—the latter being the same as croup and occurring in tickety children. Perhaps the deficiency of calcium led to a relatively hyper-excitability of the nervous system, and such irritations as adenoids supplied the necessary stimulus. He discussed the laryngeal crises of tabes and their relief by local anaesthetization of the larynx, and the relief of functional aphonia by faradizing the laryngeal tonsil. Dr. W. H. Kelson (London) emphasized the fact that the ventricular bands formed a false glottis which at times became spasmodically closed. He discussed the difficulty of distinguishing between spasms of the adductors and paralysis of the adductors. The muscles which closed the airway happened to be stronger than those which opened it, and therefore the tendency of any nerve irritation was to cause closure. The excitability of the reflex mechanism was greater in children and especially in sleep, when the cortical centres were depressed. Dr. Peter Macdonald, the President, Mr. William Hill, Dr. A. J. Wright, Dr. Dan McKenzie, Mr. Somerville Hastings, Dr. Davidson (Queensland), and Mr. Mark Howell all spoke.

Mr. William J. Leighton (Manchester) read a paper on organotherapy in diseases of the ear, nose, and throat. He mentioned MacCallister's work on the relation between sepsis in the tonsil and other organs and thyroid activity. Many conditions organotherapy formed a useful adjunct to other treatment, but it was difficult to lay down rules. He mentioned MacCallister's work on the relation between sepsis in the tonsil and other organs and thyroid activity.

however, a large number of mentally unstable and intellectually deficient people who for various reasons cannot be segregated, but who, nevertheless, are a source of anxiety and need help and guidance. We can do much for such individuals by supervision from childhood onwards, by extending our social welfare organizations, by finding work fitted to their abilities, by protecting them from adverse influences, by creating out-patient clinics, and by organizing hospitals for uncertified cases. We cannot, however, "change a leopard's spots," and the psychiatrist always feels that behind his work the sinister shadow of heredity looms large. How, then, can these persons be prevented from propagating? I think educational methods would do much. If the youth of the country and people generally were taught some of the general principles of mental hygiene, and were instructed more especially as to the importance of marriage and child-bearing, many thoughtless unions would perhaps be prevented. I certainly think that definite knowledge would do something to lessen the birth of the unfit. Too much reliance, however, must not be placed on reason where the sex impulse is concerned, because the blindness of love is notorious.

I have the feeling that my observations terminate somewhat inconclusively. Perhaps they could scarcely do otherwise as our problem concerns human beings, and each case we deal with is a complex personality which cannot be treated by cut-and-dried methods. Each case is unique and demands individual consideration. It is something to recognize that mental disorder is a problem worthy of attention, and I think that the community as a whole is beginning to realize that those who are condemned to go limping through life through no fault of their own are deserving of sympathy and consideration.

R. A. GIBBONS, M.D., F.R.C.S.E.,

Gynaecologist to the Grosvenor Hospital for Women.

#### STERILIZATION OF MENTAL DEFECTIVES.

THE fact that in this Section of Medical Sociology there is a discussion on mental deficiency to-day speaks volumes for the increasing interest which is surely being taken by those who are earnestly endeavouring to do whatever may be in their power to improve the condition of the mentally unfit; who take a serious view as to the necessity of preventing the advent of any but healthy children, and who have at heart the well-being of our race.

As the time at our disposal is very short, I must confine my remarks to showing briefly that, according to statistics, mental deficiency is on the increase; to emphasizing the cause of this increase; and especially to attempting to discover whether, in the opinion of those present, the time has arrived for the adoption of radical measures to limit the number of mentally deficient children brought into the world, and thus gradually reducing their number to a minimum.

In Great Britain and Ireland, according to the most recent figures collected, there were over 178,000 mentally affected, and without burdening you with actual figures I may say there has been a steady increase over former numbers. Such figures cannot, of course, include many who are taken care of by their relatives or friends at home. With such appalling numbers, it is imperative that everything in our power should be done to ameliorate this state of affairs, and the sooner radical means are taken seriously to endeavour to effect an improvement, the better it will be for our country. It is certainly remarkable that, notwithstanding the large increase in these numbers, so much hesitation concerning the adoption of drastic measures for their reduction exists. I need not refer to the numbers affected in years previous to those I have quoted, but as it is evident that there is a distinct increase in the figures the question must be asked, To what is this to be attributed? Without hesitation, the answer must be "Heredity." Doubtless many cases are the offspring of parents showing signs of a breakdown even before marriage, owing to continued anxiety, coupled with the wear and tear of modern life, etc. But even in the case of parents both of whom appear well and strong, it will be found in the vast majority

of cases that there is a neuropathic strain traceable in the family history of the father or mother. Heredity is the most wonderful sequence of the fusion of the sexual pronuclei, for the resulting germ contains the images of two individuals, and is therefore capable of transmitting their characteristics to the individual developed from it. This being so, we know that nothing we can do will alter the result of a marriage between two individuals with a serious neuropathic history, for it has never been known for two mentally defective individuals to become the parents of a normal child. It is stated that no less than two-thirds of all feeble-mindedness is due to heredity.

It may be said that much may be done by the upbringing of a child in a satisfactory environment, and although it is true that heredity and environment cannot be studied apart with reference to the development of children, yet, however carefully a child may be brought up from infancy, environment cannot do everything when the child is mentally defective. I have known children brought up in the most satisfactory environment, who have been well enough to go to school, have been sent away for misbehaviour, and who in spite of everything which care and wealth could do, have turned out to be liars and thieves.

Although heredity has such a profound influence in the causation of mental defectives, there are two classes of mentally defective children whose condition may be brought about by other causes. One is that of a child brought into the world after a long or difficult labour, when the mental development seems very prone to be interfered with; and the other that of the last child of a large family, when the mother may have been worn out by repeated labours. In both these classes there may be no neuropathic history on either the mother's or the father's side.

The Mental Deficiency Act of 1913, which does not extend to Scotland or Ireland, includes under the term "mentally defective" idiots, imbeciles, feeble-minded persons, and moral imbeciles, or those who from an early age display some prominent mental defect, coupled with vicious or criminal propensities, on which punishment has little or no deterrent effect.

The desire of all who seriously consider this matter must be not only to do what is best for these defectives, but to stop their propagation. In this Act defective children are included over the age of 7 and up to the age of 16. By the age of 16 there is ample time to be reasonably certain how much benefit can be effected by treatment, by segregation, mental hygiene, or any method deemed advisable in any individual case. The Act mentioned is an elaborate one, drawn up with the view of taking every care of the mentally deficient. On careful reading it will be seen that the Government has spared no expense in endeavouring to carry out treatment, whether by giving to the Board of Control authority for establishing and maintaining institutions, or, with the approval of the Treasury, acquiring any land or erecting any building. Moreover, careful regulations are drawn up as to the management of institutions for defectives, including—and this is important—the study of improved methods of treating mental deficiency. Therefore it may be safely stated that at the present time in this country mental defectives have as much care bestowed on them as is possible in any public or private institutions, and, of course, the cost to the State is enormous, although it is provided that, unless Parliament otherwise determines, the aggregate amounts so paid shall not exceed £150,000 in any financial year. Since this Act has been in force experience may suggest improvements. It is possible there may be still defectives existing for whom the Act does not provide sufficient care or training; nevertheless it has been carefully drawn up, giving full authority to the Board of Control, and yet, notwithstanding these methods of treatment, the number of cases is on the increase.

Now although I have mentioned what the cost may be, I feel sure that no one would wish to diminish that amount if benefit accrues from the treatment adopted. I consider it highly desirable that any amount of money should be spent where there is any chance of doing permanent good, and by the time a girl or boy arrives at the age of 16 sufficient evidence has been gained of the mental state to see whether any real benefit has been effected by the amount of care and attention bestowed. If there be no

those segregated, we have to remember that we must deal with many who are not segregated, and never will be. Careful regulations for sterilization would be drawn up, and the operation never performed except, as already stated, with the sanction of one or more alienists.

Let me say in conclusion that if there be any more effective methods of treatment, by all means let them be adopted, but considering the perfectly appalling increase in these cases, and the fact that whatever treatment has hitherto been carried out has been insufficient to lessen these numbers, in my opinion it is time to try something which may prove to be more radical, and that therefore sterilization should be given a fair trial—one which must naturally extend over many years.

It may be that even this treatment may not be the final solution of the problem, and I am sure that if found wanting the members of our profession have too much good sense to allow it to continue. The laws of inheritance and the most careful statistics alone would prove whether sterilization of the unfit is really effective, and, if adopted, ought to continue, or whether it should be banished as a failure.

W. NORWOOD EAST, M.D.,  
Senior Medical Officer, Brixton Prison.

#### THE INCIDENCE OF CRIME AND MENTAL DEFECT.

THE practical working of the Mental Deficiency Act has now been effective for a sufficient time probably to enable a fair estimate to be made as to the incidence of crime and mental defect.

In my view it is of first importance to be correctly orientated on this matter. Hyperenthusiasts are liable not only themselves to expect impossible benefits from the Act, but to lead others also to share their views, and unless it is clearly recognized from practical experience what the Act can, and cannot, do in the prevention and treatment of crime, an unfortunate reaction may ultimately set in, and the beneficial results actually obtained become disregarded. For it is obvious that those sections of the Mental Deficiency Act dealing with crime will only be utilized by the judicial and administrative authorities so long as they, and the public, are satisfied with the results. Such satisfaction cannot in the long run be gained and maintained if we anticipate greater achievements than actual facts permit.

It would appear from the writings of some authors that the majority of prisoners are insane, defective, or psychopathic. Darrow of Chicago, for instance, in his recent work on crime, says, "There is no longer any question that a large number, say probably from 10 to 20 per cent., of the convicted are in fact insane at the time the act was committed, and that the demented, the imbecile, and the clearly subnormal constitute more than half the inmates of prisons." Dr. May of the Boston State Hospital, in his recent valuable book on mental disease, records that "27.5 per cent. of the prison population as a whole have been found to be mentally defective."

I do not presume to criticize these American figures, but similar statements are made from time to time as applying to this country—statements the Mental Deficiency Act has shown to be erroneous if we accept the statutory definitions of defect as embracing the various forms of amentia, and statements, moreover, which are liable to be injurious, for they suggest that our present methods of treatment can prevent a larger amount of crime than is in fact possible at the present time.

It is essential in dealing with crime to discriminate between mental deficiency and inefficiency. The Mental Deficiency and Lunacy Acts provide for the rational treatment of the defective and insane criminal, but a large group of mental inefficients, consisting of subnormals, cases of undeveloped psychoses, psychoneuroses, and neuroses, remain outside the scope of these Acts. At the present time the scientific treatment of this group of criminals is unfortunately prevented by economical considerations, but it is important to bear this in mind constantly, and not attempt to stretch the definitions of mental deficiency to include any of them; otherwise the true defective may suffer from the consequent administrative and judicial difficulties and com-

plexities that will arise. Moreover, as further progress in the treatment of the mentally inefficient criminal lies in the direction of this border-line and psychopathic group, its existence should be insisted upon at all times, and clearly distinguished from the defective and insane, both in the witness-box and elsewhere.

We are only concerned here with amentia, and the number of criminal defectives in England and Wales (that is, defectives who reach prison) is considerably less than is often supposed. During the year 1921-22 of 66,715 prisoners of all kinds received into prison 223 were certified as mental defectives. In the year 1922-23 of some 60,983 prisoners received the number of defectives certified was 246.

Brixton is a remand prison, and to us are sent all the male remand and before trial prisoners in London, Middlesex, Surrey, and portions of Kent, Hertford, and Essex. Therefore we receive our cases from several million of the population, and deal with considerably more insane and defective prisoners than any other prison, a large number being remanded solely for a psychological examination. In this work I am assisted by two skilled whole-time colleagues. During the two years April 1st, 1921, to March 31st, 1922, and April 1st, 1922, to March 31st, 1923, respectively, 8,277 and 7,740 remand and trial prisoners were received. Of these, during the first year 792 were remanded for special psychological examination, of whom 72 were certifiable as mental defectives under the Act. In the second year 725 were remanded for a similar examination, and of these 67 were certifiable. This comparatively small number may be taken, I believe, as an accurate estimate, for our cases are examined also by the county medical officers, with whom we find ourselves in entire agreement as to diagnosis. The county medical officer and prison medical officer are liable to regard the cases from somewhat different angles, and some disagreement might be expected, perhaps, but the fact that there is none is, I think, reasonable testimony that the figures quoted may be relied upon as fairly representing the facts.

Rarely a case in whom no report by the court is called for and in whom nothing indicative of defect has been noted on the reception examination or during detention may escape diagnosis, and a certain number of elderly prisoners are met with in both remand and convicted prisons who would be certifiable under the Mental Deficiency Act if any history as to early age was available. But such cases, although to some extent increasing the figures I have given, would not alter the end-result—namely, that the mental defective is not met with in prison in the large numbers which some accepted before precision and standardization in diagnosis were acquired by the passing of the Act.

The individual psychological study of prisoners has been conducted for very many years in certain prisons, unrecognized outside official circles; but the Act has brought the necessity for such study forcibly to all those dealing with crime, and it is reasonable to suppose that some slight increase in the total number of prison defectives may be found in future, as the influence of the Act in preventing crime becomes more fully appreciated generally.

The defective is less frequently met with in prison than the insane. This is so not only in Brixton, but is shown by the total figures of the last five years referring to the prisons throughout England and Wales; the fact is noteworthy, for the number of defectives in the country is said by Dr. Tredgold to be slightly in excess of the insane. A gratifying feature in the general prison figures is that the proportion of defectives certified under Section 9 of the Act (after conviction) is steadily falling, whereas the number certified under Section 8 (before conviction) is steadily increasing.

A mere consideration of figures such as I have given fails to represent the amount of benefit arising from the Mental Deficiency Act in its relation to crime. It has amongst other things demonstrated the relative value of intelligence tests, and shown that certification in criminal cases ultimately depends upon a capacity to earn a living and abstain from crime. It has demonstrated more clearly the difference between deficiency and inefficiency, between the defective and the subnormal. It has shown that no criminal offence is pathognomonic of defect; that, for instance, arson, which was at one time regarded as being particularly

It was a happy idea of M. TERNER's to bring out a book on ocular sematology; the pathology of symptoms, for so far as we know, the only other work with a similar title is that of Beard, which was published in the United States more than ten years ago. The author insists that to do justice to this segment of the eye a work of five divisions is necessary; these he names as follows: the corneo-scleral cap, conjunctiva, and anterior chamber; the ciliary body, iris, diaphragm, and pupil; the lens and its suspensory ligament, glaucoma, and sympathetic ophthalmitis; the external ocular muscles; and lastly, variations in position of the eye in the orbit, exophthalmos, and enophthalmos. The present volume deals with the first of these sections. It is divided into two parts. In the first, treating of anatomy, physiology, and clinical examination in the living subject, stress is laid on the importance of using such more modern aids to examination as the corneal microscope and slit lamp. In the second part the diseases of the corneo-scleral wall, inflammations, ulcerations, cicatrizes, and degenerations of the cornea and inflammation of the sclerotic, conjunctivitis and affections of the conjunctiva are considered. The last part is devoted to contusions, ruptures, and perforating wounds of the globe. It will be seen that the table of contents is sufficiently comprehensive; on his work, and shall look forward to receiving a further installment, in which the rest of ocular sematology will be reviewed.

METABOLISM AND DERMATOLOGY.

While some dermatologists are striving to explain the phenomena of eczema and urticaria in terms of anaphylaxis or in substances with which the patient is brought somehow into contact, another school is trying to correlate these and other dermatoses with definite chemical changes in the blood.

Dr. L. E. PULAY is a distinguished member, and his recent book, *Stoffwechsel und Haut* forms a very interesting contribution to the study of blood chemistry, especially in its relation to dermatology. There can be little doubt that work on these lines must sooner or later yield valuable results. It is the effort to find a scientific basis for the popular explanation so often given by sorely tried physicians to their unfortunate patients who constantly demand to know the cause of their condition, that there is "something the matter with the blood." Frequently this is no doubt, strictly speaking, quite true, but in the present state of our knowledge of biochemistry it is usually impossible to state with any degree of scientific accuracy what biochemical fault is difficult to detect with a piece of litmus paper.

Dr. Pulay has concentrated his attention on the estimation of the volume of the blood corpuscles. All these difficult estimations and investigations Dr. Pulay succeeded in getting carried out for him on numerous patients in the laboratories of Vienna. The amount of work and time necessary for their completion in each case is obvious to anyone who has even a modicum acquaintance with the methods of blood chemistry. It may be permissible to inquire whether there is any dermatologist in London at the present time, where

conditions in general are far superior to those existing in Vienna, who would be able to command facilities for such extensive and laborious researches unless he founded and subsidized his own laboratory. As regards the results obtained, it is too early to draw any definite conclusions, but in some diseases Dr. Pulay has provided interesting data. Patients suffering from eczema appear to show excess of uric acid, cholesterolin, and sugar in the blood. Urticaria. Another interesting point which emerges from the blood investigation of urticaria is that in all cases there is an excess of calcium. It will be remembered that some years ago Sir Almonroth Wright advised the exhibition of calcium salts in urticaria with the idea of increasing the viscosity of the blood and thus hindering exudation into the tissues and the production of wheals. According to Dr. Pulay, to give calcium salts to a sufferer from urticaria is comparable to the transport of coals to Newcastle; this may explain the many clinical disappointments experienced by those who have followed Sir Almonroth Wright's advice in this matter. One of the conditions Dr. Pulay has studied in some detail is lupus erythematosus; he comes to the conclusion that in the chronic discoid form of that puzzling disease abnormal intermediate products of metabolism allied to uric acid are acted upon by light as a catalyzing agent. The author is a pioneer in a field where the work is difficult and laborious. It may easily be that the present methods are still inadequate to the task of elucidating the chemical problems of dermatoses associated with errors of metabolism, but it must be conceded that he is trying to advance in the right direction, and his book deserves study both by dermatologists and biochemists.

MEDICAL CHRONOLOGY.

We welcome the appearance of the *Chronologia Medica*, compiled by Sir WALTER POWER and Mr. THOMPSON, because books of that class are often the means of widening the circle of those who take an interest in the important subject of the history of medicine. The book will also appeal to the more instructed in the subject, for in the handy form in which it is issued it affords a ready means of verifying dates and other facts connected with the history of medicine and science generally. Other books, it is true, have been written which give full and accurate information concerning medical writers and their works, but they are unwieldy, occupy many volumes, and do not carry the chronology of medicine and science down to our own times. Hutchinson and Hank have done more for medical biography than most men, but the extent of those works renders them not very accessible for the purpose of rapid reference.

In the book before us the attempt has been made to give in chronological order a brief biography of all those who have advanced the subjects of medicine and science. But in the small compass in which the book is contained it was obviously impossible to do more than indicate briefly the most important works and the discoveries made by each man. The chronological form in which the work is written necessitates a reference to the index at the end of the volume if information be desired concerning any particular person, but the index is accurate and may be trusted. Besides biographies, the book contains excellent lists of the dates of the discovery of drugs and the foundations of universities.

Works of this kind which deal with dates, periods, and names must conform to two cardinal principles: they must be accurate, and they must be complete. One fact stated inaccurately may become the genesis of an error which may be perpetuated for ages. Then again in absence of important names in a book of this kind may prejudice the reader should he fail to find an account of the particular person concerning whom he desires information. We find the book accurate and trustworthy, but we do not find it as complete as it should be. The amount of work and time necessary for their completion in each case is obvious to anyone who has even a modicum acquaintance with the methods of blood chemistry. It may be permissible to inquire whether there is any dermatologist in London at the present time, where

On the other hand, take the truant child, disheartened, mischievous, backward, and examine his endowment, find out what would interest him, and what he could do, what his powers of attention were, how long he could attend without undue fatigue, and what special ability he had; then give him an environment in which he could develop his abilities, such as they were, not trying to grow figs on thistles, but giving the thistle as good a soil as it could utilize, and one would have a happy, contented, docile, productive individual, doing work, manual and not of a high grade, but such as was very useful to society and to himself. After all, the personal comfort of the other members of society was to a large extent dependent upon those who had not enough initiative and outlook to be discontented with the small manual tasks.

The speaker supposed it was not as necessary to mention to that audience as to audiences on the "other side" the danger of applying in a rigid way any schematic psychometric standards to individuals—of saying, for example, that because a child had an intelligence quotient of 70 or 75 per cent., therefore it was necessary to do this or that. Experts had told them that, applying these tests in a certain factory, they had found half the operatives mentally deficient, greatly to the astonishment and dismay of the manager, who said that these men were his best workers, contented, loyal, and steady, and that he could not run his factory without them. In all these estimates attention must be paid to the environment and to the individual's adjustment thereto, as well as to the individual considered as a person apart.

With regard to segregation, he thought that one of the psychological motives which made the public eager for measures of segregation had been omitted by Dr. Devine. People were impatient of the atypical in their midst because the presence of these people hindered the smoothness of their own lives. People did not wish to be bothered with these defectives, and if they were bothered they wrote to the newspapers or rung the municipal authorities up on the telephone. These defectives annoyed us, they upset our arrangements, and therefore we wanted them segregated in some place where they would not interfere with our garden parties. The speaker thought it very necessary to emphasize the responsibility of the community for its mental defectives. If the number of mental defectives were taken at 0.5 per cent., and were multiplied by the millions of the population, the total would certainly appear appalling, and institutional maintenance impossible. But if, on the other hand, they thought of that 0.5 per cent. being assimilated by each hundred, the problem was reduced to its true proportions. It was not too much to expect 200 people to look after a weak brother or sister with consideration, or those interested in the education of the children of such a community to see that the individual who was mentally retarded was given special opportunities, that his environment was taken into the educational purview, and that when this child left school some liaison would be maintained between the school and his industrial environment, so that the school might know where an adolescent of limited mentality might be placed, and a certain amount of supervision might be continued. Was it too much to look forward to the time when teachers, judges, and physicians would have some interest in these problems, and in every community people would join together in care for the mentally defective? In reading Keith's *Antiquity of Man* he noticed that in every part of England where any remains of the palaeolithic or neolithic period were to be found there appeared to be some local antiquary keenly interested in the subject. He wished that there might be in every community a group similarly interested sympathetically in the man of the steel age. There was a tremendous fund of goodwill and intelligence available in every community if it could only be organized.

It was part of the responsibility of the medical profession to see that these problems were faced. The patient had gone somewhat out of fashion for the last twenty years, owing to the advent of the laboratory animal, who was so much easier to handle. But in the study of neuroses the patient had been reintroduced. They had found that in treating a neurosis they had to treat a sick person

at grips with destiny. These studies should be placed in the medical course at the very beginning. In the medical school it should be possible for the class to be transferred from the study of the individual organs to the study of the individual organism and the problems it had to meet. At the universities psychology was still being taught along purely metaphysical lines, forgetful of the fact that Aristotle, who was a great metaphysician, was also a great biologist. He wished such teachers would remember that the proper study of mankind was man—not merely the reaction times in the laboratory—and man, moreover, in relation to environmental conditions. When that was better realized, medical students would get an outlook on life which would be most helpful to the community, and the professions of law and teaching, and indeed every cultured person, would in consequence get a certain new insight into the responsibilities of individual citizenship.

#### SIR FREDERICK MOTT, K.B.E., M.D., F.R.S.

##### HEREDITY AND SOCIAL CONDITIONS AMONG THE MENTALLY DEFECTIVE.

SIR F. W. MOTT gave an account of a comparative inquiry on the heredity and social conditions among certain insane, mentally defective, and normal persons which he had initiated and controlled. The investigation was commenced some ten years ago by Miss Agnes Kelley in Haggerston. In 1915, under a research grant of £300 from the Board of Control, she continued the investigation in a more systematic manner in Bethnal Green. Sixty cases in each of three groups were examined, the first group comprising adult patients from the London County Council Mental Hospitals; the second, high-grade mentally defective children from special schools; and the third, normal children from ordinary elementary schools. The investigation was carried out, under the speaker's direction, at the Pathological Laboratory at Claybury. He could only state briefly the conclusions. A certain dissociation was seen between the types of stock that gave rise to insanity and those that gave rise to mental deficiency. Pedigrees of asylum patients showed considerably more insanity than mental deficiency among the relatives. Conversely, mental deficiency was very much more prevalent than insanity in the family histories of the special school children. There was more mental deficiency among the asylum cases than there was insanity among the mental defectives. The general level of intelligence and health among the brothers and sisters of special school children was poor, and distinctly below that of normal children. The intelligence of the children of asylum patients appeared to be more uneven, and though many were bright and intelligent, children who were erratic, unstable, dull, or backward were frequently reported. A great variety was seen in the type of stock in the asylum group. There were some pedigrees in which the individuals were living independent, useful lives, working at good trades, earning good wages, and intermarrying with respectable families; the patients themselves earning their own living and supporting their families before the mental breakdown occurred. There were at the other end of the scale families of a degraded type, the whole family low wage-earners, frequently of loose morals, living in poverty-stricken homes, and intermarrying with equally poor stocks. Such families had weakly, uncared-for children, and were intermittently on the parish. Good trades and high wages were even less common, and were, in fact, rare in the mentally defective group. Though there were some exceptions, the general level was poor, and there were many unskilled workers and casuals. There was a corresponding dead level of poverty in the home conditions of the majority of these cases, and the incapable (though often well-meaning) mother was very conspicuous in this group. In few of the asylum cases, and among still fewer of the mental defectives, could the home conditions be described as good, while one-third of the homes in each of these two groups were classed as "homes in which the food was quite inadequate, the clothing very poor, and bare necessities were lacking." The normal group showed a decided improvement in industrial conditions and in the care of the home and children,

expenses of participants were defrayed and the whole assistance, tenable in most of the great hospitals of Saxony. The various institutes of the University of Leipzig are described. It may be hoped that the Rockefeller gift will provide Leipzig with a hygienic institute not inferior to that of Leipzig. Whether anything comparable to Professor Sudhoff's historical-medical institute, with its printed library of 16,000 volumes and manuscript collection of more than 20,000 examina, is a probability of the near future, will continue the reader that much is to be learned from Germany. Probably he will regret that circumstances still seem to prevent full scientific co-operation and frank exchange of ideas with the medical profession of Germany.

# HOSPITAL REPORTS.

The first volume of *The Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Virginia*, is a record of great activity displayed by the staff of a private unendowed hospital with 50 beds, which in 1921 dealt with 841 patients and had 20 deaths (2.4 per cent.). The price of a room is from 4.50 dollars a day, but the question of medical and surgical fees is not mentioned. The volume contains sixty-four papers including three short accounts of the management of the hospital, records of interesting cases, four of which have been previously published in the *Surgical Clinics of North America*, and collected papers published elsewhere. There are forty contributions by Dr. J. Shelton Horsley on surgical and gynaecological subjects, among which are addresses on the ideals of the surgeon and on biological principles in surgical practice; in the first of these he follows R. C. Cabot in advising that a patient if told anything should be told the truth, and that when this is done tactfully it upsets the patient much less than is usually believed; he adds that if a doctor deliberately deceives a patient, he cannot expect any more confidence than would be given to a chiropractor or an osteopath, for there is little to choose between honest ignorance and knowledge combined with deliberate intent to deceive. This author's other papers touch on nearly every branch of surgery; the alimentary canal naturally receives much attention, and experimental investigations are related on reconstruction of the common bile duct and on reversal of anastomosis which has been employed in cases of thrombo-genic obstructions in the lower extremity or arterio-venous anastomosis. Among Dr. Warren T. Vaughan's eleven papers on internal medicine that on the "Philosophy of Medical Diagnosis" compares the process to the work of a detective, and insists that the study of functional pathology has succeeded the structural pathology of the last quarter of the nineteenth century. In their article on "Post-operative Dietotherapy" Dr. Warren T. Vaughan and Miss N. H. Van Dyke, dietitian to the hospital, show the futility of albumin water as a food, and point out that patients should leave the hospital weighing at least as much as they entered it. Miss Helen Lorraine's account of "Medical Illustrating" contains a condensed history of the subject. The concluding paper by Dr. J. S. Horsley, jun., on the anatomy of a six-legged dog, a duplicate monster designated "dipygus dibrachius tetrapus," is like the rest of this finely produced volume, admirably illustrated.

# NOTES ON BOOKS.

In the seventh edition of *Sir William Whittaker's Dictionary of Treatment*, the surgical sections have been revised by Mr. T. S. Irwin, and Professor R. J. Johnson has brought up to date his original articles in the gynaecological section. The work as a whole has been well brought up to date so as to include some account of botulism, Epstein's diet in Bright's disease, the intracardiac injection of adrenaline in the treatment of diabetes. The only error which we have been able to detect after a fairly close scrutiny of this excellent work is the attribution of the pathology of the "fourth disease" to the late Mr. Clement Lucas instead of to Dr. Clement Davies (p. 887). A medical work which has reached its seventh edition requires no further recommendation, but we may point out to those not familiar with it that this volume possesses the great advantage of including articles on obstetrical and gynaecological subjects which are omitted in at least two other well known dictionaries.

With its July number the *British Journal of Surgery* enters upon its eleventh year of issue. It may be congratulated on the high standard it persistently attains both in its articles and in its production. It may fairly be said that the *British Journal of Surgery* is the most beautifully produced scientific journal in the world, and its coloured illustrations attain a technical standard which is unsurpassed even by the best art periodicals. The long continuance of the war greatly handicapped the production of the journal by doubling, and at one time actually trebling, its cost, but by the support of its subscribers it was able to weather the storm. With the commencement of the present volume the publishers announce that they and themselves are practically to return to pre-war conditions; the type has been improved, and the pages increased to 200 in each number.

*Collected Papers from the Washington University School of Medicine*, Vol. I, 1931. (London: Henry Kimpton, 1933. (Med. 8vo, pp. 1079; 247 illustrations, 60s.)

*A Dictionary of Treatment, including Medical and Surgical Terminology*. By Sir William Whittaker, M.D., D.Sc., LL.D., M.P. Seventh edition. London: Baillière, Tindall, and Cox, 1933. (Demy 8vo, pp. viii + 1102 25s. net.)

*Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Virginia*, Vol. I. London: Henry Kimpton, 1933. (Med. 8vo, pp. 560; 218 figures, 37s. 6d.)

be regarded from the point of view of the child, of the State, and of the race.

From the standpoint of the individual there could be no question whatever that it was the duty of the community to go ahead and do all it could for all defective children, but from the standpoint of the State and the race the question arose as to whether the education of the mental defective could be justified on the ground of expense. The expense was stated to be £75 per annum for each child in a residential school, and £25 per annum for each child in a day school. His experience as medical officer for a residential special school had convinced him that the education of the higher grade child was more than justified. From the race point of view, of course, it was possible to urge that education was not only a waste of time and money, but was actually harmful. There were at present in England and Wales 201 special schools, with accommodation for 16,266. As the number of children ascertained to be defective by the Board of Education was 31,000, some 15,000 at least had to be provided for, and he believed this figure to be much too low. In the London special schools there was accommodation for 1½ per cent. of the total number of school children, and if this were taken as a guide in estimating the number of defective children in England and Wales the figure would be 80,000 defective children, for only 20 per cent. of whom there was accommodation in special schools.

The first of the causes for this lack of provision was an absence of co-ordination between the different local authorities, and the second the ignorance of the medical profession. The medical student went through his curriculum—certainly in the speaker's own time—without hearing of mental deficiency or knowing what it meant or how to diagnose it. He quoted some remarks by Sir George Newman in *Medical Education in England* to the effect that although the general practitioner stood in somewhat peculiar need of knowledge of mental conditions, yet at present the student was taught nothing of the make-up of the normal mind, and that the medical student ought to be given a clear account of the content of modern psychology in language free from the mere technicalities of provisional hypothesis. Therefore (said the speaker) it was evidently the opinion of the Ministry of Health that what was wanted was something in the way of education in psychological medicine for the medical student. This was still more important when it was remembered that there were some 2,000 medical officers, whole or part time, engaged in the school medical service. The third cause for the present lack of provision was absence of accommodation, and the fourth the difficulty of getting and training teachers, for it was impossible to educate these children without a specially trained teaching staff. Next came the vagueness of the definitions in the Act and the lack of uniformity in the standard of educability. He reminded the Section of the duties of the local education authorities under the 1899 Act, with its definition of defectives, but said that at present it was not known where to draw the line between the dull and backward child and the mentally defective child, or between the defective child who was educable and the imbecile. The first point, before dealing with any question of methods of education, was to determine what children were to be educated. Dr. Campbell in his admirable speech that morning had passed a little too much ridicule on the definite demarcations that had been laid down for different grades of mental defect. The speaker thought that the failures that Dr. Campbell got in America were possibly due to the fact that the standards there were higher than those in common use for children in this country. It was necessary to have a uniform standard of educability well laid down to pertain to every area in the country. Another point was that education was of no use whatever unless the child was going to be provided for when the education was finished. It was the usual practice in London not to notify any child unless that child's mental defect was very marked; this meant that many children went out from school without any supervision or any provision of employment or assistance. Under the Trade Boards Act it was possible to employ mental defectives at a lower wage, but the difficulty at present was the

fear of exploitation of the mental defective. Some method of placing children in employment, in addition to notification and supervision, must be applied, with possibilities of graduated payment, and safeguards against exploitation of the defective.

The speaker was unable, owing to the time-limit for speeches, to cover all his points, but he urged in conclusion that in order to arrive at the accurate diagnosis and classification of types of defectives it was necessary to educate medical students and to institute post-graduate courses.

Dr. E. LEWYS-LLOYD (Towyn, Merionethshire) congratulated the officers of the Section on their splendid programme and on the very high quality of the papers. The expression had frequently been used in the discussion, "the education of the medical man." He feared that the medical man needed educating so far as mental deficiency was concerned. On taking up his present appointment as a medical officer of health he had to confess that, although he knew something of lunacy, he knew so little of mental deficiency that he felt it necessary to attend special courses, and he thought the same thing must be true of the average medical practitioner. Too often an effort was made by some visitors to obtain the discharge of cases who were certified for antisocial conduct, especially sexual offences, on the ground that in the institutions they were performing very useful work and should be earning their living in, say, domestic service, and so save expense to the State. He did not think that this was a sound policy.

Sir JOSEPH Venco (South Australia) referred to the number of mental defectives in the population, not merely those of school age, but those who had left school, and who would remain mental defectives all their lives, also to the various degrees of mental defect, from absolute idiocy to a slightly subnormal mentality. These two circumstances constituted the great difficulty in dealing with them, first, as regards their education, which demanded separate classes and perhaps separate teachers, even in comparatively small schools; secondly, after leaving school, as regards their vocational training, which would require special institutions; thirdly, after they were full-grown and fully taught, when they were still mentally defective and required supervision, either by segregation in an institution or by special and continuous oversight in their homes or their workshops or both. This was necessarily a costly undertaking, but would probably be the cheapest and the best and most humanitarian method of caring for them. He was not persuaded as to the desirability of sterilization, and he thought this method should not be performed until such continuous care and supervision as he had spoken of had been given a full trial.

Mrs. HODSON (Eugenics Education Society) considered that Dr. Macfie Campbell's remarks about the slow, silent work of nature in removing by the third generation or so the mentally defective offspring were rather misleading. The researches to which Sir F. W. Mott had drawn attention showed rather a different state of things. In working out the heredities of families quite a number of pedigrees had been found in which four generations had shown quite clearly, if not the same type of mental defect, at all events some abnormality which made public assistance necessary. In many stocks mental disorder was singularly richly scattered. The processes which held good in past times whereby, through apparently cruel means, the race was kept pure, no longer operated to-day. For how long this natural law had been set aside it was not possible to say, but undoubtedly it was set aside now. Not only had families been found in which there was a strong mental defect persisting through four generations, but a number of families of high mental quality, individuals attaining to the level of genius, had been known to disappear or nearly disappear by the third generation. Sociologists everywhere should urge that the most careful records be kept so that the hidden factors at work might be better discovered, and some factor of selection be called in to

population would be rapidly eliminated. But this was not so. The mentally unstable and excitable, the eccentric, and all those persons who could not properly be called mentally deficient, were liable to become the progenitors of mentally deficient children. A considerable proportion of the people who were apparently normal did produce mentally deficient offspring. This there was a good deal of the unknown about this matter. The more such inquiries as that to which Sir Frederick Mott had directed attention were pursued the better, and it was well worth the while of the Board of Control or the Government to subsidize through some channel or other similar researches.

There was a discrepancy between Dr. Devine and Sir Frederick Mott. Dr. Devine argued that insanity and all minor degrees of mental instability were almost equally liable to result in the production of mental deficiency in the next generation. Sir Frederick Mott, however, showed that there was a differentiation between the ancestry of the insane and the unstable and the ancestry of the mentally deficient. All they could say at present was that these inquiries ought to be pursued, and that they held out a promising field by which they could get to know a great deal more about heredity in this connexion than they knew at present.

Personally he was of opinion that segregation was the proper method of control rather than sterilization. But it was worth while clearing up certain points with regard to the latter method. Dr. Gibbons had said—and the words so impressed him that he took them down—that sterilization did not alter the life of the individual in the slightest degree. This brought them at once to the difference between the methods of sterilization. The complete removal of the essential sexual organs would make a difference to sexual desire, but the more usual method of sterilization would not make any such difference. If, therefore, the sexual desire remained unaltered, the large proportion of sexual offences committed by these mentally defectives would remain. What, therefore, was gained by sterilization so far as the immediate case was concerned? Even with sterilization there would have to be just as much segregation as before, possibly more, because nobody knew what the effect might be upon the internal secretions which appeared to govern these matters. Therefore one had not really helped matters economically by sterilization, and one had perhaps given a false sense of security amongst the people immediately concerned and amongst society at large which might easily lead to the increase rather than the diminution of venereal disease among this class. When, therefore, it was remembered how little was known about heredity in this connexion, when it was realized that the effects of sterilization must in any case be limited and could not cover the whole ground, and when it was seen to be necessary to take the same communal means of segregation after sterilization as before, it seemed that the case for sterilization was as yet by no means proved.

These were some of the impressions which the day's discussions had left upon his mind. He thought it had been well worth while to hold a Medical Sociology Section again this year as part of the Annual Meeting, and that the choice of the subject had justified itself. A good deal of missionary work was required to make the public understand the reality and the importance of this question. A good deal of work was needed also to make the medical profession appreciate the same thing. He was not one of those who believed it necessary that the medical student when he graduated should have been taught all about these matters. Given the right kind of medical education, especially following upon the right kind of preliminary education, the graduate would have sufficient knowledge and quickness through a post-graduate course and through the experience of life to adapt himself to what was required of him in some special branch. But many who were in middle age felt that they did not yet understand human nature, and the young man or young woman in the early twenties could not be expected to have achieved much in that direction.

He desired to close the proceedings of the Section by calling attention to a very wise remark uttered by Dr. Macfie Campbell earlier in the day. Dr. Campbell had

said that they must not be alarmed by the numbers of these people in their midst. It sounded a dreadful thing that one in some 250 of the population should be a mentally deficient person. It was an appalling thing in bulk, but if it were put the other way round he was sure it would appeal to a people like the English. Here were 250 normal persons charged collectively with the care of just one unfortunate individual. Were they not prepared to take it up? It would do good to the community which gave as well as to the individual who received. He was quite sure that the English people would give it an adequate and sympathetic response.

An adjournment was made during the meeting of the Section to see a film illustrating the education of mentally defective children, shown by Miss Evelyn Fox, of the Central Association for Mental Welfare.

## The Sections.

### BRIEF SUMMARY OF PROCEEDINGS.

(Continued from page 181.)

#### SECTION OF MEDICINE.

Thursday, July 26th.

On July 26th the Section discussed "Heart disease in early life—etiology, prevention, and treatment," with Dr. J. Odery Symes in the chair. Dr. Reginald Miller (London) said the subject resolved itself largely into the consideration of acute rheumatism. The chief change in the last fifty years appeared to be a reduction in the frequency of the severer manifestations. This progress was due to clinical work rather than to public health administration, earlier diagnosis and more efficient treatment being in the main responsible. But rheumatism still remained one of the serious affections of this country. Dr. Miller considered the factors hindering progress under three heads: (1) The problem of rheumatic infection—the most important; (2) the problem of heart disease in rheumatic subjects; (3) the problem of cardiac crippling in rheumatic heart disease. He enumerated the most urgent questions awaiting solution: (1) What is the underlying connexion between rheumatism and poverty? (2) What is the origin of repeated relapse, and how can it be prevented? (3) How can we give long courses of treatment to our many heart cripples? Dr. G. A. Allan (Glasgow) emphasized the magnitude of the problem. Forty to fifty thousand school children in England and Wales had organic heart disease, and the percentage doubled during the compulsory school age. He discussed the relationship of tonsillitis to rheumatic infection. Was the tonsil the site of entry, or the home of the organism? Did scarlet fever ever produce heart disease, or did it predispose to rheumatic infection? Chorea demanded a special inquiry. He laid stress upon the education of students in the points of differentiation between rheumatism in the adult and in the child; treating rheumatism by pharmacological doses of salicylate was playing with it. If the results of work in different parts of the country could be correlated and sifted much useful information might be obtained. Dr. Allan proposed the following motion, which was seconded by Dr. Reginald Miller and carried unanimously at the conclusion of the meeting:

That the Council of the Association be recommended to appoint a special committee to consider the best steps to be taken to combat the grave menace to the community arising from chronic cardiac disease.

Dr. J. G. Emanuel (Birmingham) said that active infection of the heart demanded rest in bed; if no active infection was present a damaged heart required exercise. Physical signs, with the exception of pericardial friction, yielded evidence of past infection, but did not help in the recognition of active disease. Recent infection was shown by pyrexia, anaemia, and loss of weight. Salicylate had not diminished the incidence of rheumatic carditis; it was not a specific. There was a danger in its administration in that by relieving pain and pyrexia the child might be allowed up too soon. Hospitals, auxiliary to existing general hospitals, were badly required where children might lie until

are still believers in the doctrine of signatures. He relates many instances given to him by a village herbalist, who said, for instance, that pine-cone garlic was good for toothache because the scales of the cone resemble teeth. At the end of the interview, however, the herbalist seems to have given himself away by claiming "wonderful cures, if they have faith." But Mr. Kipling will not let us off altogether. He seems to regret that we have not the simple and courageous faith of our fathers, exclaiming—

We are afflicted by what we can prove,  
We are distracted by what we know.

Perhaps the modern herbalist does little positive harm, although, as in the Crodon case, by preventing prompt treatment he may be the indirect cause of harm. There is no evidence that he employs deadly plants, of which there are not a few in this country, for criminal purposes. We should almost be sorry if he and his stock of dried plants disappeared from the humbler walks of life in which he moves, whether his disappearance came by suppression or by evolution into Membership of the College of Herbalists proposed to be established under the egregious lieutenant-commander's Act.

### THE PARLIAMENTARY SESSION.

The parliamentary session, which began on February 13th and on August 2nd was adjourned to November 13th, has been more important than evenful. Apart from the anxieties attendant on foreign affairs, its proceedings have lacked striking interest, for no large measures of far-reaching change were introduced. But after-war conditions have continued to place grave responsibility upon administration and have made demands for legislation which, although unheroic, has had to be framed with much care and considered with deliberation. This remark applies especially to such matters as unemployment, housing, and agriculture.

All these subjects concern medical men, but for the most part indirectly. As to the first named, some credit may fairly be assigned to the Ministry of Health and its forerunner—the Local Government Board—that the physical condition of children does not appear to have suffered in the industrial depression. In regard to housing, the scheme which Mr. Chamberlain formulated and carried through was rather useful than grandiose; it was conceived with the object of encouraging local authorities, by the aid of money voted by Parliament, to erect dwellings economically in limited number where most needed, and of helping rather than hindering private enterprise—the lesson of harm from heavy subsidies in tending to raise expense having been learned. A wise precaution has been the establishment of a committee to watch the rise in the cost of material. In reference to rent restriction, Mr. Chamberlain, threatened by agitation on all sides, steered a middle course, to maintain until 1925 the existing restriction subject to modification, which should be useful in opening up property for occupation. By another neat adjustment the Minister extricated landlords in Glasgow, and in some other parts of Scotland, from the "no rents" entanglement. To meet the conditions of agriculture the Government has reduced the proportion of rates to be paid and, in another measure has authorized the setting up of agricultural credit societies and the grant of loans in certain cases to meet the exigencies of farmers holding heavily mortgaged land. In all these matters whatever desires

The small-pox outbreak was taken in hand very seriously by the Ministry. Mr. Chamberlain in his answers to questions has demonstrated that he is thoroughly alive to the danger. He pronounced recently taken a step which may determine the balance in favour of vaccination for a good percentage of children. Hitherto there has been issued with registration certificates a form to facilitate conscientious objection. In future, parents will be required either to obtain a form from the vaccination officer or to make a declaration in similar terms. It should be added that in the frequent references to Health Insurance across the floor of the House, Mr. Chamberlain has, as the lawyers say, shown himself fully "seized of the subject."

There is no need to dwell upon the continued responsibilities pertaining to the Pensions Department. They are being gradually reduced by final awards, but the imagination of the public by making plain the vastness of the medical and surgical work still carried on. One departure of the year is the establishment of a small mental hospital exclusively for ex-service men. Major Tryon has frequently rebuted the utterly unwarranted insinuation that medical boards have sought to reduce allowances. He has given facts and figures to prove that, on the contrary, the reductions have been slight in comparison with the gains in health under treatment, and that the assessment of patients suffering a set-back have been revised accordingly. His fine tribute to the medical profession in its application of science to the relief and cure of those broken by the great war has been greatly appreciated.

The passage of the Dangerous Drugs (Amendment) Bill was made smooth by Mr. Bridgeman in consultation with the Medical Committee acting in conjunction with the British Medical Association. The measure imposes drastic maximum penalties for offences, and at the same time avoids interference with doctors requiring such drugs, either in emergency or at the same time avoids interference for societies and the grant of loans in certain cases to meet the exigencies of farmers holding heavily mortgaged land. In all these matters whatever desires

Lords.

The small-pox outbreak was taken in hand very seriously by the Ministry. Mr. Chamberlain in his answers to questions has demonstrated that he is thoroughly alive to the danger. He pronounced recently taken a step which may determine the balance in favour of vaccination for a good percentage of children. Hitherto there has been issued with registration certificates a form to facilitate conscientious objection. In future, parents will be required either to obtain a form from the vaccination officer or to make a declaration in similar terms. It should be added that in the frequent references to Health Insurance across the floor of the House, Mr. Chamberlain has, as the lawyers say, shown himself fully "seized of the subject."

There is no need to dwell upon the continued responsibilities pertaining to the Pensions Department. They are being gradually reduced by final awards, but the imagination of the public by making plain the vastness of the medical and surgical work still carried on. One departure of the year is the establishment of a small mental hospital exclusively for ex-service men. Major Tryon has frequently rebuted the utterly unwarranted insinuation that medical boards have sought to reduce allowances. He has given facts and figures to prove that, on the contrary, the reductions have been slight in comparison with the gains in health under treatment, and that the assessment of patients suffering a set-back have been revised accordingly. His fine tribute to the medical profession in its application of science to the relief and cure of those broken by the great war has been greatly appreciated.

The passage of the Dangerous Drugs (Amendment) Bill was made smooth by Mr. Bridgeman in consultation with the Medical Committee acting in conjunction with the British Medical Association. The measure imposes drastic maximum penalties for offences, and at the same time avoids interference with doctors requiring such drugs, either in emergency or at the same time avoids interference for societies and the grant of loans in certain cases to meet the exigencies of farmers holding heavily mortgaged land. In all these matters whatever desires

the paroxysmal types—asthma—and the true infective type was the mucous diathesis in which vaccine also was disappointing; this group, including mucous colitis, was very difficult to treat: the cardio-vascular, nervous, and digestive systems must also receive attention. Old bronchitis might be killed by too robust attempts to upset their habits. Dr. Donald Hall (Brighton) said he had found autogenous vaccine of value. Dr. Perkins, in reply, said the discussion appeared to have emphasized the fact that chronic bronchitis was secondary, the importance of educating people to an open-air life, the necessity for removing underlying conditions, and for treating the patient as well as his lungs.

#### SECTION OF SURGERY.

*Thursday, July 26th.*

WHEN Sir Henry Gray, President of the Section, took the chair at the second session he found a large audience gathered to hear the discussion on the treatment of acute primary infections of the hand. It was obvious as the discussion proceeded that it provided a very considerable amount of interest, although apparently a subject of minor importance. Mr. Wilkie (Edinburgh), who introduced the discussion, pointed out the importance of the subject from both a pathological and an economic point of view. The anatomical considerations were, first, that the lymphatic network was so very full and free; secondly, that the cellular tissue, especially in the pulp of the digits, was divided into spaces by dense fibrous septa, and that infection of the tissue led to great tension, often with necrosis. In addition, in the palm of the hand there existed two large cellular spaces. Further, the arrangement of the tendon sheaths in relation to these spaces demanded accurate anatomical knowledge. The two main types of infection were the lymphatic and the suppurative. The lymphatic were those as a rule from a minor, almost insignificant, prick or scratch, and rapidly fulminating generalized streptococcal infection took place. It was an incorrect thing to incise such a finger, as a free opening invariably led to a more rapid spread in the opened-up tissues. In regard to the treatment of suppurative cellulitis freedom of incision, rest in the initial stages, dressings of the nature of hot antiseptic wet dressings, and at a later stage a certain amount of freedom of movement, followed closely Nature's methods. He advocated strongly the use of Bier's elastic bandage in the acute lymphatic infections, along with a large dose of polyvalent antistreptococcal serum. In operating on these cases it was essential to apply a tourniquet and administer a general anaesthetic. Early accurate diagnosis was the crux of the management of hand infection; for lymph infection without suppuration the treatment should be on essentially conservative lines; for suppurative infection in tissue spaces or tendon sheaths prompt and free drainage with early systematic functional exercises should be the guiding principles. The discussion was continued by Mr. Max Page (London), Mr. Saner (London), Mr. J. E. H. Roberts (London), Mr. Mullally (London), Mr. Handfield Jones (London), Mr. Burrows (Portsmouth), Mr. Mamourian (Ashton-under-Lyne), Mr. Cuthbert (Gloucester), Mr. Begg (New Zealand), and the President. Some variety of opinion in regard to situation of incisions and the application of moist or dry dressings was expressed. All the speakers agreed with the introducer of the subject in the essentially conservative treatment of the streptococcal infection, and on the necessity for operating in a bloodless field under a general anaesthetic in the suppurative types of infection.

Mr. A. A. McConnell (Dublin) read a short paper on the diagnosis of brain tumours with the assistance of x-ray photographs, taken after the ventricles of the brain had been aspirated and filled with air. He had to admit that ventriculography was a difficult operation and was attended with danger; but it had its uses in demonstrating varieties of hydrocephalus and the situation of pressure with obliteration of the anterior or posterior horns of the ventricles of the brain. Mr. Geoffrey Jefferson (Manchester) gave an account of six cases with only one death; it was his opinion that the method was only applicable where the diagnosis of tumour was certain, but its localiza-

tion uncertain. Mr. Percy Sargent (London) said that his experience of this method was that the difficulty lay in the interpretation of the radiograms. He went on to describe a method of localizing pressure on the spinal cord by tumours by the injection into the spinal theca of an oily substance called "lipiodol," which was impervious to the x rays. This method was of value in delimiting the lower part of a tumour, an important point from the operative aspect, because the neurologist could only define the upper limit of the tumour.

The surgeons of the Royal Hospital, Portsmouth, followed the lead given them by surgeons in the other cities in which the Association had met by operating in the mornings before the meeting of Sections, and also by giving demonstrations of cases in the afternoons. On Wednesday Mr. Munro Forde performed the operations of the day before an appreciative and numerous audience, and Mr. Childe demonstrated a series of cases on the same afternoon. Mr. Burrows demonstrated cases on the afternoon of Thursday, and Mr. Childe performed operations on the morning of Friday. At all of these supplementary meetings there were good attendances of keenly interested members.

*Friday, July 27th.*

"Anaesthetics from the surgeon's point of view," at the third session of the Surgical Section, while discursive, led to diversity of opinion in materials and methods and to uniformity of opinion in regard to the relationship of the surgeon and the anaesthetist and the welfare of the patient. Mr. Wilfred Trotter, who introduced the subject, showed how the sympathetic understanding of one another's work was indispensable between surgeon and anaesthetist if the full advantages of modern surgery were to be available to the patient. A surgical operation demanded for its complete success something more than the mere exercise of special aptitude and knowledge. The successful management of anaesthesia needed so full a knowledge of the actual surgical conditions that there might well be in the future a closer and closer approximation of the training of the anaesthetist to that of the surgeon and a more and more complete assimilation of the anaesthetist into the surgical team. Many of the most valuable methods of inducing anaesthesia were definite surgical operations in themselves, and seemed to ensure the inclusion of the anaesthetist in a share of the operation. In certain operations, such as those of the mouth, nose, pharynx, the relation of anaesthetist and surgeon had tended to be rather confused and difficult to regulate. It was in these specially that the anaesthetist would be likeliest to be found joining the surgical group of participants. Mr. Trotter discussed the various methods of inducing anaesthesia known and practised by himself. He regarded ether as the nearest approach to an anaesthetic of general use; chloroform as a drug which had its own proper field and for some uses of which no effective substitute had been found.

Sir W. de C. Wheeler (Dublin) thought that various factors operated in promoting a perfect anaesthesia, and both surgeon and anaesthetist should exercise wise judgement in considering the nature of the operation, the type and temperament of the patient; even the temperament and habits of the surgeon must be considered. He dwelt on two practical points—one in relation to cases of sudden collapse, where ordinary means of artificial respiration failed, but where he thought (in at least 12 cases) he had saved the patient by inflating the lungs by blowing through the facepiece of an ether apparatus closely applied to the mouth. This was a plan of ancient usage and he commended it in certain desperate cases. He thought that the so-called ether pneumonia was not due to the ether itself, but to the imperfect descent of the diaphragm. He advocated also local anaesthetics in conjunction with general anaesthetics. Dr. A. E. Boyd (Dublin) favoured colonic ether anaesthesia; he had practised with great success the injection into the rectum of a certain quantity (1 oz. to every 20 lb. of the patient's weight) of a solution of olive oil and ether, in equal parts, sometimes with the addition of a drachm or two of paraldehyde.

It was estimated that \$2,000 a year would be required, and it was found that the financial position of the hospital would not warrant the expenditure. The Board made an approval for financial help to commence the work to the directors of the Prudential Assurance Company, basing it upon the facts that the proposed research work would undoubtedly promote longevity and the development of a healthier and more virile race, and was thus of distinct value to a great assurance company. As a result, the directors of the Prudential Company agreed to provide the money required for the first year. This, so far as we are aware, is the first occasion on which an insurance company in this country has contributed to the cost of investigations which, if we regard the matter merely from a financial point of view, nearly touch its interests. We shall not be far wrong if we say that the trend of much of the observation and research in medicine during the last decade has been to show that the seeds of much disease in later life and premature death in the working years are sown in childhood. If we can keep away the man with the taxes we may look forward to a better expectation of life in the future.

#### THE ROCKEFELLER FOUNDATION.

THE review of the world-wide activities of the Rockefeller Foundation during 1922<sup>1</sup> by its President, Mr. George H. Vincent, is of special interest because it contains a summary of the work done in its first decade. The Foundation was incorporated on May 14th, 1913, under a special charter granted by the State of New York and with an initial endowment of one hundred million dollars by Mr. John D. Rockefeller. During the last ten years this Foundation has received no less than one hundred and eighty-two million dollars from Mr. Rockefeller, has expended 76,800,000 dollars, and has pledged its future income to the extent of 15,600,000 dollars. A few weeks after the establishment of the foundation the Rockefeller Sanitary Commission, which since 1910 had been fighting hookworm disease in the Southern States, was reorganized as the International Health Board, and became a department of the Rockefeller Foundation. In 1914 the China Medical Board was created to further medical education in the new Oriental Republic; and in 1919 a Division of Medical Education was set up. By means of these agencies the Foundation has during its first ten years co-operated, chiefly in public health projects and the improvement of medical education, with the governments and institutions of sixty countries. In accordance with the object of the Foundation—the prevention of disease—for which an efficient general medical education is essential, the trustees have concentrated attention upon the closely related subjects of public health and medical education. During the war the Foundation spent nearly twenty-two and a half million dollars on various forms of activity—beneficent and in the interests of research; for example, the Public Health Service efficiently protected from malaria 43 areas in the vicinity of army camps in 15 States. The international exchange of information between workers was interrupted by the war and to restore this commerce in ideas to something like its normal state the Foundation is taking a vigorous share by disseminating medical periodicals in Europe. A summary of the development of modern medicine is followed by copiously illustrated descriptions of what the Foundation is doing for medical education and for public health. Two million dollars have been allotted to provide a site, building, and equipment for the School of Hygiene near the British Museum, which our Government has undertaken to maintain.

The vital statistics for 1922 of non-native officers in West Africa show a relatively favourable record. The average personnel of the services through the year was 3,220, and the total number of deaths 26, or 8.0 per 1,000; the average length of service at death was six and a half years, which is only six months short of the seven years required for pension. This death rate shows a decrease of 33.3 per cent. on that recorded for last year, and constitutes a record. It is worth noting that it compares not unfavourably with the rate of 6.8 per 1,000 obtaining in East Africa in 1920, the last year for which East African records are available. The improvement is mainly due to a reduction of 50 per cent. in the rate for the Gold Coast. The rate of invaliding is less favourable: 67 officers, or 20.8 per 1,000, were invalided, after an average service of 7.66 years, as against 16.6 per 1,000 in 1921, whilst 32 out of a total of 76 officers pensioned were pensioned on account of ill health. The corresponding number for 1921 was 21 out of a total of 62. Of the total deaths 5, and of the invalidings 18, are recorded in the age group with the central age of 35, the highest combined figure in other age groups being 6 deaths with the central age of 40, but the high mortality is balanced in this case by a lower invaliding rate. It is suggested in the remarks on these statistics that the figures indicate that the longer tours of service under the new regulations, which have been in force throughout the year, are not having any adverse effect on the general standard of health of Government officers in West Africa; but it must be remembered that the longer tour of service might well produce a more immediate effect upon the invaliding rate than upon the death rate, and it seems premature to advance any opinion upon this point.

#### VITAL STATISTICS OF NON-NATIVE OFFICERS IN WEST AFRICA.

From the Society of Medical Officers of Health we have received a copy of a leaflet for the use of parents entitled *Prevention of Decay of Teeth*. It is concise and clearly worded, and the instructions are such as can be carried out in daily life. Perhaps stale bread might be advised in place of "crisp toast" or "twice-baked bread," and we may be allowed to point out a misprint—"delay" for "decay." The point, however, we have in mind is that many others we have not seen, issued by different bodies; the substance of all is very much the same, yet in detail the daily hygiene of the teeth is an important matter, and we suggest that greater weight would attach to these leaflets if all bodies interested in such propaganda issued one and the same set of instructions.

#### PREVENTION OF DENTAL CARIES.

<sup>1</sup> West Africa: Vital Statistics of Non-Native Officials in West Africa: Returns for 1922. Published by the Crown Agents for the Colonies, 4, Millbank, London, S.W.1. Price 6d.

<sup>1</sup> The Rockefeller Foundation: A Review for 1922; A Summary for the First Decade. By George H. Vincent, President of the Foundation, for the Year, 1922. (Fp. 59; 28 illustrations.) New York, 1922.

months of pregnancy. A note of warning was necessary in connexion with the employment of spinal anaesthesia in cases of normal labour: the expulsive power of the uterus was diminished and forceps delivery would probably be required. The paper was discussed by the President. Dr. Sidney Forsdike then read a communication on the treatment of uncontrollable uterine haemorrhage by radium. He had treated forty-five cases who had all undergone various previous operations for severe haemorrhage. He emphasized the fact that all his cases had been treated by radium *in utero* after preliminary curettage. The sole contraindication to the employment of radium was the presence of chronic pelvic peritonitis. One exposure was generally sufficient. Radium produced a menopause, but without any of the ordinary symptoms attending that condition. Radium produced its results purely by its action on the endometrium. Slides were shown to illustrate the changes produced—namely, atrophy of the glands of the endometrium and great increase of fibrous tissue. On the other hand, the ovarian tissue showed no signs of irradiation unless the ovary was in actual proximity to the radium. The paper was discussed by the President, Mr. Whitehouse, Dr. Grove, Dr. John Campbell, Dr. Hendry, and Dr. Russell Green. Dr. Louisa Martindale next contributed a paper on the treatment of fibroids by Erlangen methods. The paper was discussed by the President, Dr. Forsdike, and Mr. Beckwith Whitehouse. None of these speakers could find anything favourable to say concerning this method of treatment. Mr. Lane Roberts followed with a paper on syphilis in its relation to obstetrics. The proceedings of the Section were concluded by Dr. W. R. MacKenzie, who read a paper on roentgenographic pelvimetry. He said that the short exposure necessary was not sufficient to produce any ill effect either on mother or child. The paper was briefly discussed by the President, Dr. Louisa Martindale, Dr. Hendry, Mr. Lane Roberts, and Dr. John Campbell.

#### SECTION OF PATHOLOGY.

Friday, July 27th.

In a historical review of the origin of the science of medical mycology Dr. Castellani drew attention to the fact that medical mycology came into existence long before bacteriology, but in recent times the study of bacteria has absorbed the attention of medical pathology. But more than 25 per cent. of tropical diseases were due to fungi and the part they played in morbid processes in this country was becoming more and more widely recognized. Fungi might be defined as filamentous organisms not possessing chlorophyll and reproducing either asexually by division and spore formation or sexually after conjugation by oöspores. They consisted of a vegetative part devoted to the acquisition of food and a reproductive part. Dr. Castellani defined the different types of reproductive organs—namely, gonidia or endospores, conidia or exospores, thallospores, hemispores, zygosporae, and oöspores. The difficulties encountered in the accurate scientific classification of fungi were enormous, and could not well be overcome without an extensive knowledge of botany. Classification was founded chiefly on the shape, colour, and character of the spores. Dr. Castellani then considered the biological and biochemical characteristics of fungi and showed that they behave similarly to bacteria in producing specific agglutinins and toxins, but unfortunately in many cases a large amount of non-specific agglutinin for other species was also present. He described a mycological method for the identification of various sugar and other carbon compounds. Turning to the higher fungi as agents in the causation of disease he declared that statements in textbooks that thrush was due to *Oidium albicans* were misleading, for the disease clinically recognized as thrush might be caused by many different types of fungi; most of these belonged to the genus monilia, but ascomycetes and saccharomycetes and other fungi might be responsible for this infection. He showed six fungi collected from cases of thrush and pointed out that clinically there were many different varieties of this disease.

Until a few years ago ringworm was considered to be caused by only one type of fungus, but it was now known that there were different types of ringworm caused by different organisms. The two principal types of thrush to be distinguished clinically were the white or grey-white type, extremely common, and the yellow-brownish type of rarer occurrence. In the tropics bronchial affections due to the higher fungi were quite common, but they might also be met with in temperate climates. The severity of these diseases depended a great deal on the variety of fungus present, the prognosis being most unfavourable in nocardial infections, more hopeful if of monilic or oidium origin, and comparatively good if caused by a sporotrichum, a hemispore, or fungi which were rapidly influenced by potassium iodide. The severe chronic forms of broncho-mycosis had all the customary appearances of advanced tuberculosis, for which they might be easily mistaken. Broncho-moniliasis might be a primary disease or a secondary infection grafted on to tuberculous disease. In true broncho-moniliasis when the patient got better the fungus disappeared, the administration of potassium iodide caused great relief, and the monilia isolated were pathogenic for rabbits. He classified the urethritis of hyphomycetic origin into three types: (1) with a white or yellowish discharge due to saccharomycetes, monilia or oidium; (2) with a brownish or black discharge due to aspergillus or penicillium; (3) with a red or pink discharge due to pigment-producing fungi or yeasts and bacteria in symbiosis. Dr. Castellani completed his lecture by showing a large number of slides illustrating different types of dermatomycosis. Dr. Carvadias, Professor Haswell Wilson, Dr. Dukes, Dr. MacKeddie, and Dr. Mackenzie Wallis took part in the subsequent discussion.

Owing to the pressure of other matter it is necessary to postpone publication of the full report of the discussion on diseases of the stomach.

#### SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Thursday, July 26th.

THE second day's proceedings opened with a discussion on the sequelae of epidemic encephalitis, with Dr. Hinds Howell (London), Vice-President, in the chair. An excellent discussion followed the opening paper, read by Dr. Farquhar Buzzard (London). He said that an experience of five years had enabled us to be more or less familiar with the ravages of the disease, but it was still not easy to separate clearly between the active phases of the disease and its sequelae. Such sequelae could be broadly divided into disorders of function appearing after the disease was spent and those which appeared to follow progressively upon the acute phase. He mentioned the following sequelae, discussing each in turn: (1) Mental after-effects; (2) involuntary movements; (3) the Parkinsonian syndrome; (4) disturbances of respiration; (5) hiccup and vomiting; (6) optic neuritis; (7) lethargy. The pathogenesis of the sequelae was an interesting question, but all could not be due to recurrent attacks of inflammation. Remarkable hyaline and calcareous changes had been found in the vessels, which might account for some of these sequelae. Such changes in the blood vessels were often found in the basal ganglia. In some cases of focal epilepsy localized meningeal changes had been found and treated surgically. No specific treatment was yet known. It was important to insist on a really adequate period of rest and convalescence.

Dr. G. Riddoch (London) related the case of a relapse occurring at the end of five years, and went on to give an analysis of the sequelae found in a series of cases at the London Hospital over a period of three and a half years; 83 cases had been traced and followed up; in most some defect remained. Mental defects were found in about seven-tenths of the cases, but the severer forms of defect were uncommon. Marked behaviour changes and intense outbursts of temper occurred, especially in children. On the physical side permanent cranial nerve palsies were common, chiefly affecting the ocular muscles. Tachycardia

attention of a

Welfare Fund, which was founded on the rate of a penny per ton on every ton of coal raised under the Mining Industry Act 1926.

[illegible]

one mine where dynamite was exploded in a comparatively contracted area men were forced to go in amongst the fumes with Mr. Herbert Jones afterwards touched upon quarry work in Wales to say that the industry had been neglected by the Mines Department. In North Wales there was very little protection for people emerged near the crushers, and they came away as if they had just crawled from a hot sack. It was generally admitted that if the dust did not bring about phthisis it produced silicosis.

question of insanity.—Mr. Chamberlain, replying to a lengthy question of innuendo by Mr. R. Richardson, on August 1st, said he could find no evidence that the existing voluntary board system was open to abuse. In mental institutions in his working, Mr. Richardson asked whether, in the cases of those patients who were received in private mental institutions in 1922 without being sent by a magistrate and without the provisions of Section 8 of the Lunacy Act, 1860, having been adhered to, such patients had since been discharged. Mr. Chamberlain said he was advised that that inquiry was completely falling within the requirements of the Section mentioned and did not need to be made.

*P. Leitch, M.D., Hospital.*—Major J. R. Wood asked, on August 1st, whether the Minister of Health had received any protest from the medical profession in Lancashire in regard to the appointment of the superintendent of Preston Asylum, Manchester. J. R. Wood said the Minister had received no official protest, and said the Minister of Control had received no official protest.

[illegible]

for the year 1920, amounted to Rs 3,221. At the date of the armistice there were 55 inmates, but during the year 1919 the average number was 33. The institution was now used for mental defectives by the Langkashire Asylum Board and was certified by the Board of Control. Some blocks were used for mental defectives in 1915 and since the spring of 1920 the whole of the institution had been so used. The total cost of maintaining defectives there since 1915 to March 31st in the present year was £37,318.

*Grants for Combating Venereal Disease*—Mr. A. Bennett asked, on August 2nd, whether the Minister of Health would consider the

allocation of the annual grant of £12,000 for combating venereal disease between the Society for the Prevention of Venereal Disease and the National Council for Combating Venereal Diseases; whether the Minister was aware that the latter organization was the only one to receive any State assistance; and why, seeing that the three organizations were all engaged in the same work, the Government assistance was not distributed equally among them; and whether the Government was prepared to consider the possibility of a grant being paid from the Ministry direct to voluntary organizations in aid of their work in the same field.

comparing these diseases was £7,500. He was aware that only one solicitor received State assistance. The question of Government aid for the work of such organizations would come up for review in connection with the recommendations in the Trevelyan report which was now under consideration.

after the administration of an anesthetic, and expressed the opinion that further investigation was necessary. Mr. Chamberlain promised to make inquiry with a view to considering whether further action was needed.

flying. The judgement of the approach of a cricket ball was similar to the judgement of the flying officer in landing. They had learned to insist upon something near perfection in the whole ocular arrangements: emmetropia, good muscle balance (that is, an accurate adjustment of external and internal ocular muscles), optic tracts which faithfully reported impressions, and cortical areas which received and analysed these impressions accurately. A "master eye" went with a poorer eye capable of giving false impressions, the reception of which might cause disastrous actions. In practice a wholly one-eyed man was safer in the constancy of his limitation than the two-eyed man whose disability was variable. Glare was particularly disturbing to binocular conditions and aggravated any latent defect. Wing Commander Cecil Clements said he had found defects of muscle balance of importance in certain civilian occupations—for example, amongst engineers. At a flying station similar disabilities produced serious accidents. No less than 80 per cent. of crashes occurred during landing—that is, when judgement was most involved, eye judgement particularly—and amongst the officers who were the subjects of the accidents ocular imbalance was frequent. Landsmen did not realize the immense disturbance of ocular conditions produced by an aeroplane spin, by side-slipping, and the approach to earth in landing. The strain was great on normal eyes—much greater in abnormal eyes. He thereupon detailed the tests used in these examinations. Amongst all tests the one he found of greatest service as a standard was Bishop Harman's diaphragm test. Major-General Sir William Macpherson said that the problem of the army was different: keen visual acuity was the prime necessity; provided the nature of the work allowed their use, glasses could be made use of to improve acuity. Major J. H. Gurley said that by the rearrangement of visual standards a great reduction in wastage had been obtained. Colonel Ransom Pickard commented upon the occurrence of night-blindness in conditions of uncorrected errors of refraction and the exhaustion caused by the strain of these errors. Surgeon Commander Breton said a successful gunlayer must have first-class vision; 6/6 was not enough; 6/4 should be the normal for these high-grade ratings. Further, there should be perfect imbalance for most purposes.

Major E. B. Spaeth (U.S.A. Army) spoke upon development of plastic operations for the restoration of lost eyelids and showed a number of photographs of cases. Mr. M. W. B. Oliver commented on the plastic operations. The occurrence of night-blindness in war conditions was important; occasionally it was simulated by malingers. Protection of the eyes was also important. Mr. Bishop Harman referred to the disclosure of muscle imbalance during periods of ill health due to abdominal trouble and thought that this was a parallel to the disturbances set up by the severe and sudden stresses of flying. Dr. W. Maddox thought near vision tests were not so good as distance tests, which more approached natural conditions. Major Carruthers said he had worked with Commander Clements for some months and was convinced of the importance of the work done by him, and the effectiveness of the ocular training devised by him. Mr. H. Caiger, Major A. E. Wright, and Mr. J. A. Valentine put questions on certain points; Air Commodore Munro and Wing Commander Clements replied. The President commented upon the high value of the research work done by Commander Clements and the influence this would have upon research in industrial fatigue. A paper on the lighting of battleships was read for Surgeon Lieutenant Commander R. J. Hanson, R.N.V.R. At the conclusion a resolution was passed urging the Government to carry on research in these ocular problems, which was carried unanimously.

#### SECTION OF PUBLIC HEALTH.

Friday, July 27th.

THE chair was taken by Dr. Lockhart Stephens, and a discussion on the effect on health of sewer air and drain air was opened by Professor Wynne, M.O.H. Sheffield. Dr. Wynne said he believed the recent enforced economy in public health departments had not been an unmitigated evil, as it had compelled a more careful and critical examination of the comparative value of various branches

of public health work. The same care should be taken in compelling expenditure by private individuals as in dealing with the public funds at the disposal of the M.O.H. Reconstruction of drains was often expensive, and it was necessary to consider how far the generally accepted view of the danger of inhaling drain air was justified. In face of the appalling sanitary conditions with which they were confronted, sanitarians in the last century and the framers of the Public Health Act of 1875 concentrated on the abolition of "nuisances" generally, and especially on the efficient removal of excreta. In those days faulty drainage came to be looked upon as the principal cause of nearly all epidemic disease. More recent research had shown that these diseases were not generally, and probably could not be, caused in this way, and the medical profession then fell back on the theory that the inhalation of polluted air in some way reduced the resistance to these diseases, "by lowering the vitality of the tissues." He did not understand this phrase, and all the available evidence pointed in the opposite direction. Chemically sewer air under ordinary conditions had been shown to be free from deleterious gases, and bacteriologically purer than air from adjoining streets. Men working in sewers were at least as healthy as the average, and had no special liability to the diseases under consideration. Numerous experiments had proved that animals kept in an atmosphere consisting entirely of sewer air were not harmfully affected by it. He drew a distinction between sewers merely pervious to smoke under pressure and those so defective as to permit the escape of liquid sewage into the soil. Pollution of the soil adjacent to houses with liquid sewage containing putrescible organic matter and with an enormously high bacterial content might easily become a cause of disease, but experiments showed that the discharge of bacteria into the air only took place as a result of splashing, and that their presence in the air was localized and very temporary. It was therefore important to avoid waste of money in this direction and to concentrate expenditure on the remedy of conditions that were proved to be a danger to health.

Dr. Mearns Fraser (Portsmouth) agreed that the danger of sewer air might be exaggerated, but thought it might be difficult to draw the line beyond which defects became dangerous. It was certainly necessary to prevent pollution of the soil by liquid sewage. He thought it might be dangerous to assert the harmlessness of drain air in houses. Dr. Wynter Blyth said that many of these experiments in the past had been made by people who were quite hazy as to the chemico-physical conditions with which they were dealing. The whole matter was a question of frothing or bubbles, and he had been experimenting on the power of bursting bubbles to disperse bacteria. Dr. H. Scurfield hoped that further researches would be carried out by Dr. Wynter Blyth on these very interesting lines. He had always taught that sewer air did not cause diphtheria or other infectious diseases, but might predispose to them. Without water-tight and gas-tight drains it was difficult to guard against leakage or to recognize an obstruction when this occurred. Dr. Glennie emphasized the importance from a health point of view of rats gaining access to the sewers and possibly conveying infection to the inhabitants. Dr. Wynne replied to the various points raised.

Dr. Hazleton (Sheffield) in a short paper called attention to the frequency of leakages from gas brackets and the consequent inhalation of CO and other constituents of coal gas as a possible predisposing cause of tuberculosis. He explained by diagrams the construction of the ordinary gas-tap, and how wear tended to cause leakage. By reversing the position of the tap this could be prevented. In the discussion which followed Drs. Fraser, Scurfield, and Wynne agreed that even apart from tuberculosis the conditions to which Dr. Hazleton had called attention were likely to be a serious source of ill health, and one not generally recognized.

#### SECTION OF DISEASES OF CHILDREN.

Friday, July 27th.

DR. DAVID NABARRO (London) gave a review of the work of different observers on summer diarrhoea and described his own findings in 150 cases which he had investigated with Dr. Paterson in 1921. The organisms isolated in different

The pituitary had become increasingly important, and headaches due to a derangement of the pituitary had to be diagnosed from sphenoidal disease. Diabetes, abnormal blood pressure, climacteric deafness, neuroses, hypothyroidism were all common causes of ear trouble, and were alike amenable to organotherapy. Dr. J. A. Gibb (Aldershot) read a paper on the referred pain of nasal sinus disease. The site to which pain was referred was often disregarded. Other viscera sometimes chose the same areas as did the nasal sinuses, and therefore observation should be backed by a thorough overhaul of the sinuses. The position and severity of the pain did not always depend on the severity of sinusitis. He detailed the areas for the various sinuses and gave cases illustrative of his thesis. Mr. Wright (Bristol), Mr. Woodman (Birmingham), and Dr. Jobson (Guildford) cited cases from their own experience. In the afternoon Mr. V. E. Negus read his paper upon a newly described function of the vocal cords in fixing the thorax during independent use of the fore limbs. He used facts from comparative anatomy in support of his argument. Sir J. Dundas-Grant read a short paper upon Canfield's operation upon the antrum. Mr. William Hill (London) read a paper upon *butyn* as a local anaesthetic in nose and throat work. He had found it capable of replacing cocaine in some cases, though not in all. It was two and a half times as expensive and less reliable. After the last paper Dr. Eastman Sheehan of the New York Post-graduate Hospital showed animated photographs of naso-plastic operations.

#### SECTION OF RADIOLOGY AND ELECTROLOGY.

*Thursday, July 26th.*

THE meeting of the Section was devoted to a discussion on medical diathermy, Dr. W. J. Turrell (Vice-President) taking the chair. The discussion was opened by Dr. E. P. Cumberbatch with a few words on the design of the present diathermy machines. He believed that larger and more powerful machines were needed; the machines at present made had often to be used "all out," and to give their maximum output of current. This left no reserve of power for use on occasions when the sensitive part of the machine—the spark-gap—was not in its best possible condition. The spark-gap also needed further improvement. Dr. Cumberbatch then spoke of the uses of diathermy in certain diseases, leaving infections by the gonococcus to be dealt with by a later speaker. One disease in which excellent results had been claimed for diathermy was angina pectoris; Nagelschmidt stated that after courses of treatment some of the patients remained free from attacks for months or years. Bordier spoke of the value of diathermy for the treatment of cold paralysed limbs in anterior poliomyelitis. Diathermy, in the speaker's own experience, was most valuable in the treatment of the pain and spasms accompanying haemorrhoids. Diathermy should be an efficient method of treatment of dysmenorrhoea by reason of its power to relieve congestion and painful spasmodic contraction. It should also be given a trial in cases of chronic para- and peri-metritis. Bordier recommended diathermy for coccygodynia. A few workers in the United States and Germany had tried diathermy for pulmonary tuberculosis. If diathermy possessed therapeutic action in pulmonary tuberculosis the benefit derived was likely to be due to the increase of blood and lymph supply to the affected parts, and perhaps to the increased secretion of mucus, not to a direct germicidal action, because a temperature high enough for this purpose could not be safely produced in the lungs. Dr. C. A. Robinson gave a brief account of some work which he had carried out on the treatment of gonorrhoeal affections by diathermy currents. He said that gonococcal infections of joints, of the cervix and urethra in females, and of the prostate and epididymis in males, were amenable to treatment by diathermy because by this means these parts could be heated to a temperature which for the gonococcus in these situations was lethal within the time of a treatment. Dr. Agnes Savill spoke of her experience with local diathermy for the

treatment of gonorrhoea in women. Dr. Howard Humphris, in a further paper, touched upon the value of diathermy in cases of high blood pressure. High blood pressure might evidence itself in a variety of ways, none of them pathognomonic. This was a condition in which diathermy could do very much. The therapeutics of the current in lowering the blood pressure were twofold, one the general and constitutional effect on the metabolism and the other the local effect on the vasomotor system. Other conditions in which this current could be used were gout, anaemia, and wasting diseases. Dr. Turrell considered that the way to look at this question of medical diathermy was to have regard to the mode of action of diathermy and the manner in which it would apply to the particular case under treatment. Dr. G. B. Batten described his use of intensive high frequency in the treatment of haemorrhoids; he had used this method for twenty-five years, and the more he used it the better he liked it. Dr. C. B. Heald had found diathermy useful in gonorrhoeal infections. Professor Sidney Russ dealt with a number of points on the physical side, and other members of the Section asked questions to which Dr. Cumberbatch and Dr. Robinson made brief replies.

#### SECTION OF NAVAL AND MILITARY HYGIENE.

*Thursday, July 26th.*

AT the morning session Major M. Sinclair, R.A.M.C., read a paper on recent changes in fracture treatment, illustrated by lantern slides showing appliances *in situ*, result of x-ray examination, etc. In the discussion which followed Surgeon Captain D. W. Hewitt asked whether the opener advocated a pull from screws below the knee-joint in every case, and whether the age of the patient made any difference to the method used. The opener replied that callipers below the knee-joint were used when the skin was affected, but he would apply screws in all cases with marked displacement and irrespective of age. The stretching of the ligaments of the knee-joint, said to occur thereby, he did not consider of any importance. Captain Hewitt read a paper entitled "Some general remarks on naval surgery"; in the subsequent discussion the President pointed out the need for specialization to keep abreast of modern knowledge. Dr. J. Graeme Anderson read a paper on aeroplane accidents. This was illustrated by lantern slides showing photographs of the accidents described. Surgeon Commander Digby Bell remarked on the value of such a paper in co-ordinating the medical branches of the fighting forces. Dr. Stone (Northampton) inquired whether atmospheric pressure had much effect at high altitudes. The opener replied that the scope of the question was too wide for a reply in detail. He described some of the measures taken by pilots to avoid these ill effects; the process of becoming immunized was gradual.

In the afternoon Major Sinclair gave a demonstration of special appliances for the treatment of fractures. A ward in Haslar Hospital was placed at the disposal of the Section through the courtesy of Surgeon Rear-Admiral Alexander Maclean. The demonstration included (a) special instruments used; (b) a mobile x-ray plant with power furnished from a dynamo run from the wheel of an R.A.S.C. lorry, with which x-ray photographs were taken in the ward; (c) various modifications and adaptations of Thomas's splint, with which fourteen patients were fitted for demonstration purposes; (d) an extension exhibit of x-ray plates showing fractures before and after treatment; (e) net bed; (f) set of models; (g) other modifications of splints for allowing movements of fingers or joints of affected limb. After the demonstrations the members of the Section were shown over the Haslar Hospital and joined up with the garden party in the grounds, where tea was given by the medical officers attached to the hospital.

#### *Demonstration of Physical Training.*

On the afternoon of July 25th the Section of Naval and Military Hygiene assembled at the Royal Naval School of Physical and Recreational Training, Portsmouth, for a demonstration of the methods employed at the

hospital possesses the same accommodation as when it was

Ἰησοῦς.

only 199 in 1870. Owing to this great increase it had been necessary to curtail the period of residence in the hospital during convalescence, although it is fully recognized that a longer period would be of the advantage of both mother and child. As indicating the very large part played by this hospital in the life of the community, it is mentioned that over 30 per cent. of all the births in Edinburgh and Leith either take place in the hospital or are attended by nurses from it at the patients' homes. The hospital is no longer, as it used to be, merely a haven for unmarried mothers; for in 1922 there were 1,345 married women delivered in its wards as against 327 unmarried. The out-patient department for the treatment of expectant mothers was a recent addition to the work of the hospital. This special branch of treatment, now so universally recognized, was inaugurated by the late Dr. J. W. Ballantyne, who was for many years one of the physicians to the hospital. In 1922 there were fewer than 3,224 attendances at this department. Further, the services of the hospital are not purely local, since complicated and difficult cases are sent in, not merely from the immediately surrounding districts, but from all parts of Scotland. The object of the present appeal is to build a completely new and modern maternity hospital.

A DELEGATION from the Irish Medical Committee, consisting of Dr. J. M. Day, Senator W. O'Sullivan, M.D., Dr. R. J. Howlett, Dr. J. P. Shanly, Dr. T. Hennessy, Medical Secretary, and Mr. C. H. Glick, Secretary, waited on the Minister of Local Government (Mr. E. Blythe) in the Irish Free State. The deputation was accompanied by Dr. J. Casey, Dr. P. J. Greene, and Mr. M. P. O'Malley, T.D., who attended to make special representations in connection with the salaries of the Connemara medical officers.

## Rebiew.

### BRITISH PHARMACEUTICAL CODEX, 1923.

THE appearance of the new edition of the *British Pharmaceutical Codex* will be welcomed by all those interested in the use of drugs, either as medical practitioners or pharmacists. Its general character is indicated in its full title, *The British Pharmaceutical Codex, 1923; an Imperial Dispensatory for the Use of Medical Practitioners and Pharmacists.*<sup>1</sup> The book is published by direction of the Council of the Pharmaceutical Society of Great Britain, and has been prepared by a committee composed of pure chemists, pharmacists, manufacturing chemists, and pharmacologists. Hence the origin, mode of preparation, mode of dispensing, and the actions, of drugs are all described by experts. The first edition of the *Codex* was published in 1907, and the second in 1911; supplements were published in 1915 and 1922; the present volume is the third edition.

The object with which the compilation was made is stated in the preface to the first edition:

"The scope of this work may well be defined by describing the book as an imperial dispensatory for the use of medical practitioners and pharmacists, since it contains information respecting all drugs and medicines in common use throughout the British Empire, including the principal substances and preparations which are official in the pharmacopoeias of France, Germany, and the United States, as well as those described in the *British Pharmacopoeia*. The chief aim of the work is the provision of accurate information for prescribers and dispensers, special attention being given to the requirements of those practising in the British Dominions beyond the seas."

The new edition is only slightly larger than the last and follows the same general arrangement. Short monographs on the various drugs fill about three-fourths of the space, and the *British Pharmaceutical Codex Formulary*, which gives many hundred standard formulae together with directions for their preparation, occupies the remainder. The book also contains various useful tables of constants, and a new feature appearing in this edition is a table of the coefficients of expansion of various liquids.

Medical practitioners will find the formulary of value for convenience, for it contains convenient formulas for preparations for the most diverse purposes. They range from hair lotions and corn paints to mystic compounds such as Warburg's tincture, which, we believe, is the last remaining relic of the famous old mediaeval theriac.

The monographs on drugs form, however, the most important portion of the book. In the case of each drug the monograph gives an account of the raw materials from which it is prepared, a description of the chemical and physical properties of the drug and the recognized tests for its purity, and finally the pharmacological actions and therapeutic uses of the drug are described. The account of the actions and uses of the drugs have been very carefully prepared, and all the most recent information has been incorporated, so that the *Codex* is, amongst other things, practically a textbook of pharmacology and therapeutics.

As an example of the scope of the work the case of quinine may be taken. Three pages are given to the description of cinchona bark and its preparations, and nearly three more to the chemical, physical, and pharmacological actions of quinine; in addition, short accounts are given of the properties of twenty-two salts of quinine, and there are monographs also on quinidine, cinchonine, cinchonidine, and quinidine. The description of quinine includes a short account of the properties of the quinine derivatives described by Morgenroth, and there is a separate monograph on one of these—namely, ethylhydrocupreine hydrochloride, or optochin.

A comparison between the present edition and the last shows that the whole work has been carefully revised, and that many monographs have been completely rewritten. The number of entirely new monographs is, however, small.

<sup>1</sup> *British Pharmaceutical Codex, 1923. An Imperial Dispensatory for the Use of Medical Practitioners and Pharmacists.* New and revised edition. Published by direction of the Council of the Pharmaceutical Society of Great Britain. London: The Pharmaceutical Press. 1923. (Demy 8vo, pp. vii+1669. 30s. net.)

The chief drugs which did not appear in the edition of 1911 or supplement of 1915 are acriflavine, emetine bismuth iodide, colloidal solutions, oil of chaulmoogra, dried parathyroid, quinidine, radium, and antitoxin serum.

The reason why so few new drugs of importance have appeared in the past eight years is, we believe, that pharmacological advance has been chiefly along the lines of finding new uses for old drugs, and also towards finding new and more powerful derivatives of existing compounds. The number of new monographs in the *Codex* does not of course give any indication of the changes in pharmacology that have occurred—for example, insulin is described in the new edition, but is placed under the old heading of pancreatin. Similarly the account of the action and uses of the organic arsenic derivatives, of antimony compounds, and of emetine have all been rewritten.

We have given an indication of a few of the salient features of this very valuable book of reference. We feel that the committee which prepared the work is to be congratulated on the very thorough manner in which it has been revised and brought up to date. The only criticism that we venture to make is that the work would be improved by the deletion of some of the drugs described—for example, nine pages are occupied by the description of fourteen different salts of lithium, and in each case it is stated quite correctly that the action is the same as that of the corresponding salt of potassium or sodium. The need for these compounds, therefore, does not appear obvious. Perhaps such a censorship is impossible, but it seems a pity that a useful book of reference should be encumbered with the debris of forgotten superstitions.

The general value of the *Codex* is evident to anyone who has used it. In the preface to the first edition the editors pointed out that the official pharmacopoeias only contained an account of a portion of the drugs in general use. This statement is even truer to-day, and is particularly true of the *British Pharmacopoeia*, which contains no account of many of the most important drugs we possess. It is true that various excellent supplements to the pharmacopoeias have been published, but these do not lessen the value of a book like the *Codex*, which gives a critical and authoritative account of the value of most of the newer *materia medica*.

### OCULAR NEUROLOGY AND PHYSIOLOGY.

AFTER the nine large volumes on the neurology of the eye by Willbrand and Saenger which we owe to the German publishers, it comes as a relief to find that in the small volume by DE LAPPERSONNE and CANTONNET, of which a second edition<sup>2</sup> has appeared, we have an adequate exposition of the subject. It is ten years since the first edition was published, and so many new facts have been discovered in these fateful ten years that it has necessitated a complete revision as well as a recasting of the text. It is a pity that there is no similar work of the same size and price in the English tongue, for there is a distinct need of one; meanwhile the book now under review will fill the gap in the library of the ophthalmic surgeon admirably. The first part deals with the motor apparatus, the visual apparatus, the sensorium, and the vasomotor and secretory functions; each chapter discusses its subject under the familiar headings of anatomy, physiology, clinical examination, symptoms of lesions, and semeiology. The second part of the book deals with ocular neurology in diverse conditions. This part forms roughly two-thirds of the book, and at its termination is given a very convenient schema for the examination of a neurological eye case. The second part deals with local affections in the neighbourhood of the eye, and with the nervous, digestive, respiratory, circulatory, renal, and genital systems; the final chapters are on autointoxications, intoxications, and infectious diseases. An excellent index completes a work which reflects great credit on authors and publishers; the illustrations are most helpful; the whole book forms a very compact and up-to-date manual of ocular neurology, and as such is very welcome.

<sup>2</sup> *Manuel de Neurologie Oculaire.* By F. de Lapersonne and A. Cantonnet. Second edition. Paris: Masson et Cie. 1923. (Med. 8vo, pp. 416; 113 figures, 4 plates. Fr. 20 net.)

SMALL-POX, THE VACCINATION PROPAGANDA,  
AND MALAYA

Sir,—I describe an experiment which, taken in connection with Captain Atkins's experience, may be significant. I have wished to ascertain the effect of a small-pox of the treatment described by Surgeon Commander Bastian (British Medical Journal, July 25st, 1907, p. 130), but have lacked opportunity. However, vaccination modified small-pox. Recently, after an interval of twenty years, I vaccinated myself; the lesions developed very rapidly; in a few days I had a widening area of inflammation and felt unwell; the vesicular stage was at hand; but as yet I had no fever. Thereupon, one evening, I began the treatment described by Bastian. I slept soundly, and as far as I know, did not sweat. Next day the inflammation was subsiding, and for two days more, as far as I am able to judge, I shall have no fever. About the same time I vaccinated a boy of 10, towards the end of the week his mother brought him to me. About the same time I vaccinated a boy of 10, towards the end of the week his mother brought him to me. About the same time I vaccinated a boy of 10, towards the end of the week his mother brought him to me.

THE IMPERIAL CANCER RESEARCH CAMPAIGN

Sm.—The labours of the Medical Research Council and of the administrators of the Imperial Cancer Research Fund have been distinctly disappointing, and I fear unless the promoters of the British Empire Cancer Campaign exercise their functions as to the use of the moneys they secure very wisely and very well, the knowledge gained may be equally disappointing and disappointing.

Before going to the public for the large sum of money

mal-pox, we have two consecutive diseases—the initial malady which ends with vesication (or, in small-pox community) is by them achieved; and against which the cause of nearly all the danger and all the discomfort, and which would occur in the absence of the disease. I repeat myself by all means be prevented. By way of test, I re Vaccination myself for a fortnight later. The lessons carried out of research in all its varied departments. This carrying out of research has power to afford pecuniary aid and committee should have power to award departmental. In fact I think, of course, in process of repetition no more scale. Of course, I do not suggest that cure abortion shall replace prevention (vaccination), but I do impossible to mitigate its severity very greatly, and that the vaccination propaganda would be aided as it known responses to my appeal, the Ministry admitted this; but unless the public shows decidedly that it is behind the Minister in this connection, I fear the Treasury will not and the necessary funds. In virtue of any subsidy granted by the House of Commons, the Minister of Health, officials of his department, and members of the House should be represented on the committee.

In my view, however, the Minister can assist research in other ways than by subsidy, and that, too, to an extent I refer to the clinical side of research. He alone can procure and collate that mass of clinical and other information possessed by the medical practitioners throughout the country. Through his medical officers of health and their staffs and the Registrar-General's Department every case of death from cancer notified might be investigated, not by a lay official, but by the medical officer of health himself or his tuberculosis officer, and a questionnaire drawn up for that might include all matters bearing upon possible causation. Cancer areas—and there are such—might be mapped out. Cancer houses—and it is suspected there are such—might be located. Information might be gleaned from meteorological, geological, water and food supply experts, etc. No possible avenue of approach

inclusion. They are as follows: Auenbrugger, the father of the method of percussion; Willan and Bateman, the founders of modern dermatology; Sir James McGrigor, the father of modern military medicine; James Lind and Gilbert Blane, the founders of modern naval medicine; Ray, who did so much for botany; and Stephen Hales, whose labours in connexion with physiology and physics were so successful. Besides these we think the names of Sir William Jenner, Sir Thomas Watson, Sir George Baker, William Prout, Wollaston, Blackall, Galileo, and Connolly should find a place in the work.

But apart from this criticism we commend the book for its excellence, and we hope that it will meet with such success that another and more amplified edition will soon be required.

#### HEREDITARY HAEMOLYTIC JAUNDICE.

THE book by Dr. E. MEULENGRACHT of Copenhagen on chronic hereditary haemolytic jaundice<sup>6</sup> is a valuable monograph on a rare but interesting familial disease. Claude Wilson in 1890 published an account of six cases occurring in three generations of one family, describing the condition as "hereditary enlargement of the spleen"; Murchison had indeed previously recorded incomplete notes of three cases in 1875. Minkowski in 1900 greatly extended our knowledge, both clinical and pathological, of the condition. In an account of eight cases in one family he emphasized its main clinical features—the enlarged spleen, the jaundice with bile absent from the urine but present in the stool, the excess of urobilin in the urine, and the chronic course. In one case examined *post mortem* he found that the splenic change consisted in hyperaemia and hyperplasia of the stroma. In succeeding years other cases were described, and knowledge of the condition was extended. The observations of Chauffard were the most important, demonstrating microcytosis of the red cells, the presence in them of peculiar granules, and their lowered resistance to haemolysis in hypotonic saline (*fragilité globulaire*). Chauffard insisted that the disease was one of the blood and spleen, and not of the liver. The condition became known as Minkowski-Chauffard's disease. In later years cases have been described in the British journals as congenital family jaundice or acholuric jaundice; and occasionally in America associated jaundice. Dr. Meulengracht has collected cases since 1914; thirty-four of them he had under prolonged observation; of these, twelve have been submitted to splenectomy with good results. He gives the most complete and detailed account of these cases—their clinical and family history, and the condition of the blood cells (in the operated cases both before and after operation). This large number of cases, their careful examination by modern haematological methods, and the thorough study of the literature, combine to make this book a standard contribution to the subject.

#### THE CLINICAL LABORATORY.

FIVE-AND-TWENTY years ago the general practitioner was shy at calling in the laboratory worker to aid him in completing a diagnosis, and even in the large hospitals there was very inadequate provision for rendering this assistance. Nowadays it is a daily occurrence to postpone a definite diagnosis until a laboratory report has been received, and if he would derive the maximum amount of information from that report the practitioner must be acquainted with the methods adopted in its production. For this there could be no better guide than Dr. CHARLES E. SIMON's *Manual of Clinical Diagnosis by means of Laboratory Methods*, the tenth edition<sup>7</sup> of which with its 1,100 pages—or double the number of the first edition, published in 1896—is evidence of the great advances which have been made in clinical pathology as an aid to

diagnosis. Great as these advances have been, Dr. Simon considers they are insignificant in comparison to actual possibilities, and he looks forward to the day when at every hospital of first rank there will be a real clinical laboratory, in charge of a real clinical pathologist ranking equally with the surgeon and physician. In the section devoted to the diagnosis of syphilis the Wassermann reaction is very concisely and clearly described, and a study of the details of the author's modification of the technique leads to the conclusion that his method of procedure has been well thought out. A very practical point is dealt with in the few pages devoted to the behaviour of the blood serums of different individuals and to the categorizing or grouping of different types. The importance of this grouping becomes evident when a donor for the purpose of blood transfusion has to be selected. In the past, writes Dr. Simon on page 246, surgeons have largely been in the habit of accepting donors whose blood gave rise to agglutination only but not to haemolysis when brought together with the recipient's blood.

The arrangement of the book does not differ materially from that of the immediately preceding editions. The first part is concerned with general principles and technique, and the second part—nearly one-third of the volume—with the essential factors in the laboratory diagnosis of various diseases. In this second part the author deals in alphabetical sequence and in more or less detail with a very large number of diseases in their relation to laboratory diagnosis. Dr. Simon is lecturer in medical zoology in the School of Hygiene and Public Health of the Johns Hopkins University, and in this capacity appears to have acquired a facility of expression which is noticeable throughout the volume. There is an utter absence of pedantry, and he is so seriously impressed with the importance of his subject that his enthusiasm is passed on to his readers. A great injustice would be done to the publishers if no reference were made to the excellence of the illustrations. The twenty-three coloured plates call for special commendation.

#### PUBLIC HEALTH AND MEDICAL INSTITUTIONS IN SAXONY.

WE have received a copy of a sumptuously produced volume on the public health and welfare system of Saxony,<sup>8</sup> which has been compiled to commemorate the centenary of the first meeting of the German Society of Naturalists and Physicians, held at Leipzig in 1822.

The volume contains a well illustrated account of all institutions directly or indirectly concerned in the study or administration of public health, and does not lend itself to summarization. In view of the topical interest of schemes of post-graduate instruction, we may, however, summarize the summary of activities under this heading.

The earliest foundation with this character was the Medical and Surgical Academy, which dates back to 1815. It was for long the only institution in Germany giving post-graduate instruction in midwifery and gynaecology, and to this day four-weekly courses in spring and summer are largely attended at Dresden. The next foundation was the Pathological Institute of the Dresden-Friedrichstadt Hospital (1850), where Professor Schmorl now gives post-graduate courses in pathology.

Since 1901 there has also been a special association under whose auspices combined classes are held by the staff of the various hospitals and institutions of Dresden, which cover the whole field of practical medicine. Under the auspices of a national committee, formed in 1907, courses were also given in Leipzig, Chemnitz, Zwickau, and Zittau. The various committees were affiliated to a central committee at Berlin in 1908.

The war-time spread of venereal diseases led to the institution of special courses of instruction in early diagnosis and treatment, held, in 1922, in six cities by various experts. No fees were charged, but the travelling

<sup>6</sup> *Der chronische hereditäre hämolytische Ikterus*. Von E. Meulengracht. Leipzig: Dr. Werner Klinkhardt. 1922. (Roy. 8vo, pp. vi+226; 5 plates.)

<sup>7</sup> *A Manual of Clinical Diagnosis by means of Laboratory Methods*. By Charles E. Simon, B.A., M.D. Tenth edition, enlarged and thoroughly revised. London: Henry Kimpton. 1922. (Medium 8vo, pp. xxiv + 1125; 235 figures, 25 plates. 42s. net.)

<sup>8</sup> *Einrichtungen auf dem Gebiete der Volksgesundheits- und Volkswohl-fahrtspflege im Freistaat Sachsen*. Dresden and Leipzig: T. Steinkopf. 1922. (Cr. 4to, pp. viii+303; illustrated. 8s. 51.)

of very considerable importance, for the perfunctory treatment which these cases have received, and the concealment which the law encouraged, must have had a material effect in spreading disease when the sailors returned to their homes and comrades.

stances differing from the normal fats in containing nitrogen Halliburton's well known textbook include fat-like substances that the lipids as recognized and described in Professor other pathological tissues. It seems desirable to point out of the tubercle bacillus, but of normal organs, and of

The "Queen" Book of Travel,<sup>12</sup> which has been compiled by Mr. M. HORNSBY, the travel editor of the *Queen* newspaper, is a compact little annual which has now reached its sixteenth year. In addition to a concise account of the principal British and foreign resorts it contains a large quantity of miscellaneous information, including a description of spas in Great Britain, practical hints on travelling in various countries, the names of English doctors practising abroad, and a list of books suitable for the traveller's library. The volume has fifteen excellent maps and numerous photographs of British and foreign resorts.

The volume entitled *The Older Universities of England: Oxford and Cambridge*<sup>13</sup> gives a fascinating account of their development and activities. It is based on a course of lectures delivered on the Lowell Foundation in March, 1922, by Mr. ALBERT MANSBRIDGE, who, though not educated on the banks of either the Isis or the Cam, shows a profound knowledge of his subject, and must therefore have been an unbiased and most efficient member of the Universities Commission (1919-22) appointed to consider the condition and wants of the two universities and make recommendations. The volume contains much interesting biographical material and many stories illustrative of the attitude and life of university dons; on this account alone it will be much appreciated by the sons of the universities. But this is only a minor feature in a book primarily concerned with the future of Oxford and Cambridge and how best they can fulfil their high educational mission. The line of their past development has been in the direction of becoming efficient post-graduate institutions, and the author's opinion coincides with that of Sir E. Rutherford, who has said that "the future of the universities and the reputation of the countries to which they belong will ultimately depend to a large extent on the development of post-graduate teaching." Medical matters are only mentioned incidentally, and the main reference is to Sir William Osler's appeal in his address to the Classical Association (1919) for the closer union of humanism and modern science.

Messrs. E. and S. Livingstone (16 and 17, Teviot Place, Edinburgh) have published in a small volume (2s. 6d., by post 2s. 9d.) the papers set in 1920-23 for the medical degrees of the University of Edinburgh, and the diplomas of the Royal College of Surgeons and the Royal College of Physicians of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, including the D.F.H. The same firm has published in a separate volume (price 2s., by post 2s. 2d.) the papers set in 1919-23 for the Fellowship of the Royal College of Surgeons of Edinburgh.

The "Queen" Newspaper Book of Travel: A Guide to Home and Foreign Resorts. Compiled by the Travel Editor (M. Hornsby, F.R.G.S.). Sixteenth year. London: The Field Press, Ltd. 1923. (4×7½, pp. xii + 493; 15 maps and 80 illustrations. 4s. net.)

The Older Universities of England: Oxford and Cambridge. By Mansbridge, Hon. M.A. Oxon., Hon. LL.D. Manchester. With drawings by J. Mansbridge. London: Longmans, Green, and Co. 1923. (Demy 8vo, pp. xxiv + 296; 9 plates. 7s. 6d. net.)

## THE DIETING OF THE INSANE.

CONSEQUENT upon the report of the Departmental Committee on the Administration of Public Mental Hospitals, which recommended that an attempt should be made to relieve the monotony of the diet at these institutions, the Mental Hospitals Committee of the London County Council has been considering possible improvements in the dietary with a view to more appetizing meals and an increase in food value. The dietary scale which has obtained hitherto at the London mental hospitals provides for *per capita* issues of the principal articles of food, such as bread, meat, and vegetables, for each meal. The medical superintendents believe that if the dietary scale were expressed in terms of weekly quantities for every 100 patients, and not *per capita* for each meal, with fixed formulae, it would afford them the opportunity of arranging the meals differently and of introducing more variation.

In a special report to the Committee of the Council the medical superintendents point out that the problem of dieting the insane stands apart from that of the dieting of the general population. On the one hand, the insane live under sheltered conditions, they are not subjected to the same mental and physical strain of the struggle for existence, they are under close medical and nursing supervision, and they are specially dieted on any sign of phy-

sical deterioration or disease. On the other hand, certain special precautions have to be taken: the proteins, especially those of meat, have to be restricted because they tend to overstimulate the metabolism and produce restlessness and excitement, but at the same time their undue restriction has to be guarded against because it would mean the lessening of the patient's ability to resist infections; again, the insane commonly suffer from intestinal stasis, and therefore fresh food, especially garden produce, is indicated; few of the insane take or can take really healthy exercise, and plenty of readily digested carbohydrates are essential to maintain warmth and avoid chills; vitamins also are specially important in view of the frequently lowered physical vitality of these patients and the fact that they are specially subject to auto-intoxications.

The Committee has worked out a new scale under which the daily *per capita* calorie value of the issues (including an allowance of 10 per cent. for waste) averaged over one week is not to fall below a minimum of 3,200 calories for men and 3,000 for women, presuming that these patients are on ordinary diet. It has also been decided to increase the diet in respect of fats and improve it as regards vitamins. The cooked ration of meat is, therefore, to be increased by 1 oz. per head per meal, and green vegetables are to be increased from 4 oz. to 6 oz. per issue per patient. These two modifications will increase the cost by 4½d. a head a week, or a total of £9,700 for the six months for which it is proposed the new dietary should be tried. Otherwise the adoption of the new scale, although it provides for greater elasticity in application than the present scale, should not lead to any increase of cost. The medical superintendents had asked that margarine be substituted by good Danish butter, but the Committee finds itself unable to agree to this proposal, though it is considering the possibility of obtaining supplies of better-class margarine. The revised weekly dietary for each 100 patients is to be as follows:

|                                           | Males.<br>lb. | Females.<br>lb. |
|-------------------------------------------|---------------|-----------------|
| Bread ... ..                              | 771-816       | 646-693         |
| Fats (including suet) ... ..              | 65½           | 65½             |
| Tea ... ..                                | 17½           | 21              |
| Sugar ... ..                              | 84            | 93              |

The medical superintendents have power to make certain variations as between the amounts of the different items as the result of experience, and there are regulations for substitute diets to be allowed in the case of patients unable to take the ordinary dinner. For non-working patients the scale is to be reduced by the following quantities:

|                                                                                |
|--------------------------------------------------------------------------------|
| Males: Bread 131½ lb., cheese 43½ lb., tea 3½ lb., sugar 14 lb., milk 42 pts.  |
| Females: Bread 131½ lb., cheese 43½ lb., tea 7 lb., sugar 23 lb., milk 84 pts. |

All articles of food not included in the dietary are deemed to be "medical comforts," and are to be accounted for accordingly.

THE thirty-second French Congress of Surgery will be held in Paris from October 8th to 15th under the presidency of Dr. Témoin. The following questions will be discussed: (1) Transfusion of blood, introduced by M.M. Jeanbrau, of Montpellier, and Victor Pauchet, of Paris; (2) critical study of operations for genital prolapse, introduced by M.M. Bégouin, of Bordeaux, and Savariaud, of Paris; (3) treatment of non-calculous obliteration of the principal bile ducts, introduced by M.M. P. Matthieu, of Paris, and Villaret, of Lyons. Further information can be obtained from the General Secretary, 12, Rue de Seine, Paris.

Dr. Ford Robertson.  
[Mogul, Edinburgh.]

for the spirituous analysis of the central nervous system in general paralytic cases it probably had been recognized that the dipthericoid infections of the genito-urinary, respiratory, and alimentary tracts found in these diseases, and which Ford Robertson and his colleagues were inclined to attach a causal significance, played a secondary part, being of importance in the final deterioration of the patient's health. In 1912 Ford Robertson concentrated upon the bacteriological investigations of dementia praecox and the acute insanities, and in 1921 published his book on *Theapeutic Intervention in Asylum and General Practice*. His researches indicate that the more fully the pathogenesis of insanity, as of other bodily diseases, is investigated, the more extensive are its effects, and that by the method of focal reaction one can demonstrate the pathological changes of no less an organism inhabiting the body, and among which the pathological processes are not homogeneous or unimportant.

By means of specific inoculations derived from the individual patients, and in some cases, sheep, obtained from immunized animals with specific reactions, he demonstrated that these pathogenic infections may be of many different kinds, and that they are not necessarily infectious, but may be due to non-infectious factors.

Apart from the questions of heredity, of diagnosis and classification, and of clinical treatment, in which they are naturally interested, there are at any rate two ways in which members of the medical profession may give immediate and practical administrative help. Certifying medical officers vary in their knowledge of mental deficiency and in their idea of the sphere of the special school. If such officers would adopt a relatively high standard, and as far as possible a uniform standard, of "educability" for admission to, or for continuance in, the special school it would allow of the school places, which are far below the number required, being put to the best possible use. There are difficulties in the definition given in the Act and in the form of certificate, but a wise officer can overcome these. Again, medical officers could themselves supply much of the co-operation which is lacking between the various authorities concerned in one way or another with mentally deficient children or persons. The object is to secure unity and continuity of control of the mentally deficient with a view to the prevention of personal degradation and disaster to the individual defective and of the attendant social evils. In each county and county borough there is a statutory committee for the care of defectives, and each of these has, or should have, its medical officer. Such committees cannot exercise care over defectives of whose existence they are unaware, and the discovery of defectives is left mainly to others. The Education Authorities have them in their schools or on their schedules, the Poor Law Authorities find them in their institutions, the Asylum Authorities find them in their mental hospitals, the Police Authorities find them in their courts and prisons. They are found also in inebriate and rescue homes. All these authorities or institutions have their medical officers, and if these officers would in every case, when a mentally defective person is leaving their care, communicate with the medical officer of the Statutory Committee into whose area he or she is going, a continuity of supervision and help would be secured in a large number of cases where it is now prevented by the difficulty of regulations, or by the lax or less direct methods of the authorities themselves. In all cases where more than supervision is required the necessary official steps could then be taken before it is too late. In these and in other ways the medical profession can render the most valuable help and can take its due share in the attempt to solve one of the most difficult and important problems of medical sociology, a problem the solution of which in the national interest is becoming more and more urgent day by day.

### HERBALISTS AND HERBALISM.

THAT lively legislator Lieut.-Commander Kenworthy has added to his claims to distinction by fathering a bill in Parliament "to provide for the registration of medical herbalists." The bill appears to be a kind of parody of the Medical Acts, and in the unimaginable event of its passing into law the herbalists at present in business would become legally qualified. We learn from the schedule that there is a body called the National Association of Medical Herbalists of Great Britain, Limited, and the council of this association would form the majority of the proposed "General Medical Herbalist Council for England and Wales."

We have been apt to assume that herbalists were persons in humble circumstances whose obscure lives did not often come into the limelight of publicity, and who did little harm even if they did no good, but

now and again a coroner's court lights up other aspects of their activity. For instance, at Croydon recently a boy who had been treated by one of them died of diphtheria five minutes after a doctor was called in. The herbalist, who said he had been in "practice" for fifteen years, and had previously been a bootmaker, gave evidence that he treated the boy for a common cold, and gave him something to make him perspire. It seems in this case a pity that the cobbler did not stick to his last. The report which we have seen does not tell us what sudorific herb was administered, nor how the ex-bootmaker obtained his knowledge of its virtues. Our fathers of old started from the assumption that a beneficent Providence provided all herbs for our good; every herb must, they argued, be good for some disease, and it remained only to discover the special property of each species. One way was to relate herbs with stars and to "look at the stars when a patient is ill," as Mr. Kipling has said in *Rewards and Fairies*, where in five stanzas he has given an epitome of the history of therapeutics. But, as is to be read in that poem—

Wonderful little, when all is said,  
Wonderful little our fathers knew . . .  
Whence enormous and manifold  
Errors were made by our fathers of old.

The epitome would have been more complete had the doctrine of signatures been included, but the omission may be excused on the ground that the doctrine is not very ancient when compared with the age-long belief in the therapeutic value of herbs. It appears to have been first promulgated in the sixteenth century by that extraordinary man Philippus Aureolus Theophrastus Bombastus of Hohenheim, who called himself Paracelsus and enriched the English and other languages by adding to them, unintentionally, the word "bombast." Although he was a doctor and a professor at Basle, who made great advances in chemistry and therapeutics, yet he was a very notorious quack. The doctrine of signatures may be stated in the words of Robert Turner, who wrote: "God hath imprinted upon the Plants, Herbs, and Flowers, as it were in Hieroglyphicks, the very signature of their Vertues." The doctrine of signatures professed to do this by finding either resemblances between the plant and the part of the body affected or between the plant and the cause of the disease. Thus, a plant with heart-shaped leaves is good for heart disease; the plant known from the shape of its leaves as the adder's tongue will cure the bite of an adder. William Cole, a Fellow of New College, Oxford, and a resident of Putney, carried this doctrine to great lengths. We owe to Mrs. Arber's book on herbals the following quotation from Cole, in which a most elaborate application of the doctrine occurs: "Wall-nuts have the perfect signature of the Head: The outer husk or green Covering, represent the *Pericranium*, or outward skin of the skull; whereon the hair groweth, and therefore salt made of those husks or barks, are exceeding good for wounds in the head. The inner woody shell hath the Signature of the Skull; and the little yellow skin, or Peel, that covereth the Kernell of the hard *Meninge* and *Pia-mater*, which are the thin scarfs that envelope the brain. The Kernel hath the very figure of the Brain, and therefore it is very profitable for the Brain and resists poysons; for if the Kernel be bruised, and moystened with the quintessence of Wine, and laid upon the Crown of the Head it comforts the brain and head mightily."

According to an article by Mr. L. F. Ramsey, published recently in the *Morning Post*, some herbalists

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following entrance scholarships for the year 1923 have been awarded:

or in the ordinary course of treatment. Mr. Bridgeman acknowledged his indebtedness to the profession for its good counsel, and the bill went through Committee practically as an agreed measure. Being now Home Secretary, he no longer has responsibility for seeing what can be done to minimize disease and accident amongst miners, but Colonel Lane-Fox, who has become Minister of Mines, is encouraging the same policy of investigation and research.

The adjournment, of course, leaves a variety of matters for consideration in the autumn session. Amongst these is the Mental Treatment Bill, happily through all its stages in the Upper House and ready to be taken in the Commons. Its object is to enable persons at an early stage of mental disorder to submit themselves voluntarily to treatment for a limited period.

The lamented illness of Mr. Bonar Law brought Mr. Baldwin to the Premiership early in the session. It is agreed that he has established himself not only as the leader of a party but as a Leader of the House. In him are combined the qualifications of a business man and of a lover of literature and the arts. His speeches have thus had a particular fascination on account of their accuracy in detailed statement of facts, and their literary form. It is too soon yet to judge the strength of the new Premier, but it may be said without hesitation that he has won the good-will of all sections of the House.

Any attempt to estimate the part taken by private members in the work of the session is impracticable in the short space available here. But the House generally has recognized the great value of what has been done quietly, actively, and unostentatiously by members of the Medical Parliamentary Committee, of which Dr. F. E. Fremantle is chairman.

#### SIR HAVELOCK CHARLES.

MAJOR-GENERAL SIR RICHARD HAVELOCK CHARLES, G.C.V.O., K.C.S.I., has vacated office as President of the India Office Medical Board and Medical Adviser to the Secretary of State in Council, and has been succeeded by Major-General J. B. Smith, C.B.E., C.I.E., I.M.S. (ret.). He will be succeeded as representative of the Government of India on the Permanent Committee of the International Bureau of Public Health by Major-General Sir W. R. Edwards, K.C.B., K.C.I.E., C.M.G., lately Director-General I.M.S. Viscount Peel has expressed his appreciation of the distinguished services Sir Havelock Charles has rendered to India during his tenure of these appointments, and has conveyed his thanks as Secretary of State in Council for the manner in which Sir Havelock has discharged duties, that during the war were particularly important and arduous. How arduous in certain respects these duties have been is well known to members of the British Medical Association. During the last ten years or more the Indian Medical Service has passed through a very trying period, and in every difficulty and emergency Sir Havelock Charles has shown himself its true friend. The early difficulties were in the main due to the dilatoriness of the Government of India in dealing with the situation produced by the change in the financial prospects of officers of the Service. When, owing mainly to the persistent representations made by Sir Havelock Charles to the India Office, the Indian Government at length tackled the matter, the ear raised new difficulties and imposed fresh responsibilities. The prospects of the Service have also been seriously and permanently affected by the constitutional reforms recently introduced. The discussions which preceded their adoption very plainly

indicated the direction they would take, so that their effect in checking recruiting in this country was obvious some years ago. But, the policy having been adopted by Parliament, there was nothing to be done. Finally, the report of the Retrenchment Committee dealt a further blow to the Service, and although the Government of India has been dissuaded from abolishing the appointment of Director of Public Health, the research grants have been greatly reduced. We have said sufficient to show that Sir Havelock Charles during his term of service has had no bed of roses. In spite of the fact that on many occasions he has had to take a course not always agreeable to the authorities, the honesty and sincerity of his services have been appreciated; he received the K.C.S.I. at the beginning of this year, and the *Gazette* now announces that he has been granted the honorary rank of Major-General.

#### TRANSFER OF THE SPECIAL SURGICAL HOSPITAL, SHEPHERD'S BUSH, TO ROEHAMPTON.

WE observe, from an incidental mention in an account sent to us of the work done at the Queen Mary's Convalescent Auxiliary Hospitals, Roehampton, between 1915 and 1923, that the Special Surgical Hospital, Shepherd's Bush, is to be closed at the end of this year, and that from 500 to 600 general medical and surgical cases are then to be transferred to Roehampton. It is pointed out that this will necessitate a large capital expenditure for the alteration of existing huts and the erection of new semi-permanent wards, operating theatres, etc. It will be remembered that last year (*JOURNAL*, April 1st, 1922, p. 530) a dispute arose between the Ministry of Pensions and the Hammersmith Guardians (from whom the special hospital at Shepherd's Bush is rented by the Ministry), and after the Ministry had suggested removing the patients under its care at Shepherd's Bush to huts in Richmond Park, an agreement to prolong the tenancy was happily arrived at. It seems evident that the tenancy of the hospital at Shepherd's Bush, which was formerly a Poor Law infirmary, must sooner or later come to an end. In 1921 (the figures for 1922 are not available) nearly 4,000 officers and men were under treatment at the hospital, nearly 2,500 operations were performed, and there was a total of over 101,000 out-patient attendances. An elaborate equipment of baths, gymnasiums, workshops, and departments for electrical treatment and massage has been built up at Shepherd's Bush, and this it is proposed eventually to transfer to the grounds which are available at Roehampton. It is, however, to be remembered that a large out-patient department, fully equipped for the different forms of special treatment, is needed. It can hardly be suggested that Roehampton is a place easily accessible from other parts of the London area, and apparently this problem still requires consideration. The report of the work at Roehampton goes on to say that it is hoped further to extend the benefits of the hospital there to a limited number of railway employees and others who have had the misfortune to lose their limbs in the course of their employment, and the committee hopes for financial support by donations and by the endowment of beds. Apparently the intention is to place the hospital at Roehampton on a permanent basis and to extend its facilities to the general public. This intention in regard to a Ministry of Pensions hospital, which was organized on a temporary basis for the reparative treatment of mutilated soldiers, will be observed with interest.

#### A GOOD EXAMPLE.

THE Board of Management of the Hospital for Sick Children, Great Ormond Street, has decided to establish a research department, and also to appoint a biochemist.

**ACOUSSTIC**  
GENUINE  
REGISTERED  
—MORE LAST SYLLABLE—

**A**S HAS and years before any other electrical and hearing aids were thought of, the Acousticon was the FIRST aid to hearing in its field. It is still as much a pioneer and original instrument, was helping DEAF people to hear better.

Every thousands of users will testify, "A very wonderful aid."

Every genuine Acousticon is stamped with the name Acousticon and its registered number. Beware of imitations. The really genuine Aid is the Acousticon, which is recommended by so many leading Ear Specialists. The

The old-fashioned matter of organs is illustrated—Result: Ill-health, Restlessness and bad sleep.

Dr. Sargant says in a short treatise on *Illustrations of Sleep and how to induce it*, by a Doctor (*H.D. Land*), for Doctors, a copy of which will be supplied to any medical man free on request.

"I AM glad to have had an opportunity of trying your Simplex Mattress, which I understand was supplied to His Majesty the King after his accident during the War."

"BY GIVING equal support at all points of the recumbent figure, it ensures relaxation of the muscles."

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### PUBLIC HEALTH MATTERS.

#### Hospitals and Poor Law Infirmaries: The Spahlinger Treatment.

ON the Appropriation Bill, on August 1st, Mr. Rhys Davies referred to the limited hospital accommodation and to the fact that there were in the Poor Law infirmaries of the country 30,000 empty beds, while not very many short of 100,000 people were waiting for admission to the beds of ordinary hospitals. In the case of one hospital in London at that time, there were 300 persons on the waiting list for 15 beds, an average of 20 for a single bed. He next touched upon the position at Gloucester, mentioning that employers had given notice of dismissal to those of their staffs who were unwilling to be vaccinated. He complained bitterly that such a course should be tolerated. Mr. Davies then alluded to the appeal made to the Minister by a deputation from the Lancashire Insurance Committee, suggesting that an arrangement should be made between the Ministry of Health and M. Spahlinger in regard to the use of his method of treating consumptives. He understood that the Minister of Health did not see his way financially to back a proposal which would allow of separate institutional treatment on these lines for 40 or 50 patients. The Lancashire Insurance Committee had asked to be allowed to spend part of its money in trying to secure this treatment for Lancashire patients.

Lieut.-Colonel Hodge asked the Minister to reconsider his decision. M. Spahlinger had, he said, obtained cures in 80 per cent. of the cases treated under his system. But he was not a good financier, and was in debt to the amount of £100,000 on account of the work he had done. The undertaking might be commercialized, but M. Spahlinger knew that if his method were dealt with in that manner the possibility of obtaining a cure for poor people would be minimized seriously. If the sum of £100,000 were provided those who furnished it might secure the inventor's laboratory, the whole of his estate and his father's estate. These properties would be handed over for a period of ten years. M. Spahlinger also needed money to continue his research. He asked for £10,000. He was willing that a committee should be appointed to record how the money would be spent. His wife, who acted as his secretary, and his father, mother, and sister were dependent upon him. All he sought was £2,000 a year for joint maintenance. The question was whether the Minister would find £100,000 and a subsidy of £10,000 a year for three years, with a possibility that a cure for tuberculosis would be provided. For such financial aid M. Spahlinger would give 50 per cent. of his serum and vaccine. The Minister had expressed his sympathy, but had said that he could not advise the Ministry to liquidate the debts, nor could he advise nor allow the Lancashire Insurance Committee or any other insurance committee to spend money in this way. The answer to that surely was that it was a case for courage. He asked the Minister to send out a man to Geneva to ascertain the facts and make the best possible arrangements.

#### Ministerial Reply.

Lord Eustace Percy, replying for the Government, dealt first with the assertion that while hospitals could not provide for the sick there were 30,000 empty beds in Poor Law infirmaries. The figure was quite incorrect, for it represented the highest number at the slackest season of the year, and covered a class of institutions broader than were commonly classed as Poor Law infirmaries. The actual number of empty beds in these on January 1st was just over 6,000, or about 18 per cent., and steps were being taken for a better utilization of the space in such infirmaries. He begged to be excused from entering into a discussion on the action of certain employers in Gloucester. All he could say was that if he were in Gloucester he should certainly claim the right to protect his household from what he should consider was a risk, and to do this by refusing to take into his private employment any person not vaccinated. He should regard it as a rather gross form of tyranny if the State were to tell him he was not at liberty to do so. To what extent that principle was applicable to various forms of business or industry he would not discuss at the moment. It was not quite true that no grant was given by local authorities for extra nourishment to persons suffering from tuberculosis. There was a grant in certain cases and in certain areas. It was true there was no grant given for bedding, but he protested against the assumption that it was outside the power of local authorities to take on any new activities for the prevention or cure of disease unless they had a grant from the central Government. Coming next to the question as to the Spahlinger treatment, Lord E. Percy said it was not for want of knowledge of the

interest throughout the country and the distressing need there was for an adequate and efficient cure for tuberculosis that the Ministry did not yield to the request. Nor was it because it was afraid to spend the money. M. Spahlinger had received every consideration at the hands, not only of Mr. Chamberlain, but of his predecessor, Sir Alfred Mond. Last year the Ministry sent out to Switzerland a specially qualified officer to acquaint himself with the methods, and on this officer's report the Ministry, in August, 1922, made a proposal to M. Spahlinger, which that gentleman, though unable to accept it, said he would have been very glad to accept under normal conditions. Arrangements between M. Spahlinger and the Red Cross Society also fell through. The position of the Government in this matter now was quite simple. They were interested in what was commonly known as the Spahlinger treatment. They were satisfied that there was a *prima facie* case for such further scientific inquiry as would enable medical authorities and the world in general to form a definite and final opinion as to its efficiency. But, if there was to be any question of the expenditure of public funds, Parliamentary sanction for such expenditure would be necessary, and the Government would not be justified in coming to Parliament to ask for such sanction except on the basis of adequate information and reasonable security. In the opinion of Mr. Chamberlain these conditions would best be satisfied by asking M. Spahlinger to take an early opportunity of making a full statement of his process and result to a body competent to pass expert opinion upon it. Such an opportunity was being afforded, and when M. Spahlinger had taken advantage of it they could arrive at a decision as to what action, if any, could be taken by the Government. Meanwhile, Mr. Chamberlain hoped that the appeal which he understood was now being made for funds from private sources might be successful in meeting the immediate difficulties of M. Spahlinger's position. The country might feel assured that the Ministry was watching this question with very great interest and would do everything in its power to give that assistance which trustees of the public funds could give in such cases.

#### Small-pox and Vaccination.

On the request of Mr. Bromfield, the Minister of Health, on July 31st, gave the following statistics as to percentages of small-pox cases in England and Wales for different age periods:

#### Small-pox—England and Wales.

| Year.                         | No. of Cases. | No. of Deaths. | Mortality per Cent. of Cases. | Percentage of Total Cases at Age Periods. |       |       |       |               |
|-------------------------------|---------------|----------------|-------------------------------|-------------------------------------------|-------|-------|-------|---------------|
|                               |               |                |                               | 1-15                                      | 15-30 | 30-40 | 40-50 | 50 and upward |
| 1918 ... ..                   | 63            | 2              | 3.2                           | 31.8                                      | 23.8  | 23.8  | 6.3   | 14.3          |
| 1919* ... ..                  | 311           | 28             | 9.0                           | 17.7                                      | 29.6  | 17.4  | 18.6  | 15.8          |
| 1920 ... ..                   | 280           | 30             | 10.7                          | 33.6                                      | 23.6  | 17.5  | 19.6  | 10.7          |
| 1921 ... ..                   | 336           | 5              | 1.5                           | 47.0                                      | 20.6  | 8.9   | 10.7  | 12.8          |
| 1922 ... ..                   | 973           | 27             | 2.8                           | 47.6                                      | 22.1  | 7.9   | 10.7  | 11.7          |
| 1923 (January—June inclusive) | 1,227†        |                |                               | Information not yet available.            |       |       |       |               |

\* No information received as to age of three cases in 1919.  
† Subject to revision.

The Minister has also supplied the following particulars of deaths from small-pox in Berlin and Paris:

#### Small-pox in Berlin and Paris, 1913-1922.

|            | 1913. | 1914. | 1915. | 1916. | 1917. | 1918. | 1919. | 1920. | 1921. | 1922. |

| Paris:     |       |       |       |       |       |       |       |       |       |       |
| Cases ...  | 33    | 39    | 4     | 2     | 3     | 53    | 132   | 11    | 8     | 4     |
| Deaths ... | 1     | 3     | 0     | 1     | 0     | 20    | 32    | 1     | 1     | 1     |

\* Figures not yet available.

Mr. Leach asked, on August 1st, whether the Minister of Health had any official information that it was the practice in the United States to carry out vaccination by means of a single insertion only, and that this method was as protective against small-pox as the official four-marks method adopted in this country. Mr. Chamberlain said he had no official information as to American methods. The Royal Commission on Vaccination concluded that vaccination in four places, giving a total vaccination area of half a square inch, was more effectual and gave better protection against small-pox than was afforded by one place or a less vaccinated area. Mr. Leach asked whether it was the practice in the United States to defer vaccination until children entered the public schools at about the age of 5 years; and whether the incidence of small-pox there in the case of children under 5 was any greater than during that age period in other countries, such as

NINETY-FIRST ANNUAL MEETING  
OF THE  
BRITISH MEDICAL ASSOCIATION.  
Held at Portsmouth, July, 1933.

PROCEEDINGS OF SECTIONS.

SECTION OF PATHOLOGY AND  
BACTERIOLOGY.

HECH MACLEAY, M.D., D.Sc., President.

DISCUSSION ON

REPERFERENCE TO MODERN METHODS

OF INVESTIGATION.

OPENING PAPER

ARTHUR BOLTON, M.D., D.Sc., F.R.C.P., F.R.S.,  
Physician, University College Hospital.

may continue to rise so that its highest point occurs when the stomach is empty. Such curves, which are regarded as variants of the hypersecretory type, have been called by Bennett and Kyle the "climbing type" of curve.

A large amount of work has been done in America and England in the study of these curves in different physiological and pathological conditions of the body, and as modified by drugs. From the purely clinical point of view these observations have proved of considerable value in diagnosis. The method is simple and the estimations easily and quickly done. It gives information with regard to the amount and character of the fasting contents—in some cases the duration of the secretory activity of the stomach, the percentage of free HCl and total acidity at different periods of digestion, the time of emptying of the stomach, and the presence and time of appearance in it of bile and mucus. This method is, however, not sufficiently accurate for the taking place in the stomach, because it deals only with the free HCl and neglects the protein HCl, and, more important still, the HCl which has been neutralized by alkaline salts and transformed into inorganic chloride. It is true that the percentage of protein HCl may be assumed more or less from that of the total acidity, but no account whatever is taken of the neutralized HCl in the form of inorganic chloride. We have thus no idea of the percentage of total HCl secreted, since the inorganic chlorides commonly form a considerable proportion of this total, and these curves of free acidity cannot therefore be spoken of as secretory curves at all. They merely represent the excess of acid which is unneutralized in the stomach contents. This neutralization process cannot be left out of account, because it normally regulates the acidity of the stomach contents, and in morbid processes this self-regulatory mechanism is interfered with by definite causes and with the production of well defined results. It is the chief factor in modifying the curve of acidity.

The Self-regulation of the Acidity of the Stomach

Contents.

In 1915 Bolidyff advanced this hypothesis. His evidence was based upon animal experiments. He found that when acid solutions were introduced into the fasting stomach of the dog they were rapidly neutralized down to a fixed level of 0.15 to 0.2 per cent. HCl, the total chlorides remaining always at the same level. By a series of careful experiments Bolidyff proved that this neutralization was due to regranulation of pancreatic juice from the duodenum, and he foretold that such would be found to be the case in the digesting stomach.

Bolton and Goodhart in 1922 took up this point and by making complete chloride estimations every quarter of an hour, definitely proved that, when the percentage acidity in the digesting stomach contents reaches a certain average height, regranulation of duodenal contents occurs and brings down the acid curve by neutralization. It is, therefore, a function of the pylorus to regulate the acidity of the gastric contents.

Interpretation of the so-called Secretory Curve of

Rehuss.

When the ordinary gruel meal is used the percentage of total chlorides present (that is, free HCl + protein HCl + inorganic chlorides) represents as nearly as possible the percentage of total HCl secreted. There is a small percentage of chlorine in the other digestive juices which amounts to about 0.1, so that these fluids merely act as diluents and lower the total and inorganic curve, rather less than dilute water would. The curve of total chlorides is the real secretory curve as nearly as can be obtained. It rises up with varying degrees of rapidity and remains at its high level as the stomach empties.

The rise in the acid curve undoubtedly indicates addition of HCl to the stomach contents, and it corresponds with the rise in the total chloride curve; it means that secretion of gastric juice is in progress. The fall in the acid curve does not, however, mean that secretion has stopped, because in this event the percentage of HCl would remain constant [3268]

Described by Rehuss.

1914 Rehuss in America introduced the method of plotting small fractions of the stomach contents every hour after a test meal for the estimation of the percentages of the free HCl and the total acidity, the percentages of which could thus be plotted out as curves. It was found that the average normal curve rises gradually to a maximum and drops again, forming a single peak as the stomach empties, the apex of which is reached at different periods during digestion in different cases, and the descending limb of which may or may not have reached the base line when the stomach is empty. The height reached by the apex of the peak varies between about 50 and 60. Such curves are regarded as representing the of gastric secretion and are known as iso-secretory curves (Fig. X.). Hypersecretory and hyposecretory curves, those which reach higher than or fail to reach the iso-level. Sometimes the curve never descends, or

some steps could be taken to remove this state of things. Mr. Chamberlain did not think he could usefully undertake any general action, but would be glad to consider any proposals which might be put forward by boards of guardians and the authorities of hospitals for the general use of any surplus accommodation in Poor Law infirmaries.

**Nurses' Registration.**—Replying to Dr. Chapple, on July 25th, Mr. Chamberlain said he had not taken the advice of the law officers of the Crown upon the power of the General Nursing Council to exclude from the register existing nurses who, "being otherwise qualified," made application for admission within two years from the date on which the rule, made on July 7th, came into operation.

**Oxford and Cambridge Universities.**—On inquiry by Mr. Charles Buxton, on August 2nd, Sir W. Joynson-Hicks said he had requested the University Grants Committee to take such steps as appeared practicable to obtain from the University authorities at Oxford and Cambridge returns which would be as nearly comparable as circumstances permitted with those annually supplied by other grant-aided universities. The conditions at Oxford and Cambridge, however, differed materially from those at the other universities, and as the records and accounts had not hitherto been kept with a view to such returns being made a little time must elapse before they were available.

**Insurance Medical Certificate Forms.**—Mr. Neville Chamberlain, on July 30th, informed Sir Ellis Hume-Williams that he could not undertake to withdraw books of certificates on the back of which advertisements appeared; but the issue would be exhausted at an early date.

**Therapeutic Substances Bill.**—The Therapeutic Substances Bill, having passed all its stages in the Lords, was read a first time in the Commons on August 2nd.

#### Ministry of Pensions.

The number of service patients at present in county or borough asylums for whose treatment and maintenance the Ministry accepts responsibility is 5,800.

A number of the cases examined after the final award had been set aside by the tribunal had been found to have deteriorated and had consequently received further compensation.

Approximately 1,500,000 courses of treatment had been provided by the Pensions Ministry for officers and men who were disabled in the great war.

Apart from the general provision of Section 5 of the War Pensions Act, 1921, there is no time limit affecting a claim to compensation a disabled man in respect of aneurysm.

There were only four pensioners under treatment at the orthopaedic clinic at Burnham-on-Crouch at the cost of the Ministry, but the clinic is under the control of the British Red Cross Society. The Minister could not deal with the question whether it could be made available to the other medical men in Burnham or utilized as a local hospital.

It is proposed to vacate the hospital premises at Neath in the autumn, when a suitable institution at Chepstow will be available. There are at present 169 in-patients and 78 out-patients.

The Minister of Pensions has stated that full consideration is given to opinions expressed by county and other tuberculosis officers and medical superintendents of sanatoriums with regard to the question whether the tuberculosis from which an ex-service man may be suffering is due to war service, but the decisions on the question of entitlement must rest with the Ministry, which had the advantage of the services of a sufficient number of medical men with expert knowledge of the disease to advise on this matter.

The report of the committee appointed to inquire into the cause of the fire at Highbury Pensions Hospital, Birmingham, will be published.

#### Answers in Brief.

Owing to the expense that would be incurred it is not proposed to publish the report of the Joint Committee set up by the Scottish Board of Health in 1920 to consider the relation of maternity benefit under the Insurance Act and the maternity and child welfare schemes of local authorities. The committee was composed of representatives from the consultative committee on local health administration and general health questions and of the consultative committee on national health insurance (approved societies' work).

The Minister of Health informed Sir Robert Newman there had not been an increase in deaths resulting from measles since the compulsory notification of that complaint had been abolished. The average number of deaths during the past three years had been 5,042 per annum, as compared with 7,318 per annum for the four years 1916-19 during which notification was compulsory.

The annual cost per head for the year ended March 31st, 1921, for England and Wales of the inmates of the several classes of Poor Law institutions was as follows: Homes for children, £73 18s. 7d.; Poor Law infirmaries and other Poor Law institutions for persons suffering from infirmity of body or mind, £143 12s. 1½d.; general Poor Law institutions, £73 14s. 7½d.; all classes of Poor Law institutions, £83 5s. 3½d.

Mr. Chamberlain has promised to consider a suggestion by Sir Charles Oman that in the draft order for casual paupers about to be issued, provision would be made for notices to be placed in casual wards advising that casuals should apply to see the doctor in cases of indisposition; and if unfit to travel should apply for admission to the workhouse.

The collection of information as to cancer areas in this country, or on the Continent, is receiving the attention of the Committee advising the Ministry of Health on cancer problems.

In reply to a question as to the death of a painter at West Norwood from lead poisoning, the Home Secretary said that the whole subject was receiving careful consideration, and he hoped soon to be in a position to announce the decision of the Government.

The Home Secretary has declined to introduce legislation to amend the law so as to give magistrates power to place inebriates upon the black list without their own consent.

The Home Secretary has stated that only one prison governor holds the necessary qualifications to act as a medical officer. No change in the present practice of making appointments was contemplated.

## INTERNATIONAL PHYSIOLOGICAL CONGRESS.

(Concluded from page 203.)

THE eleventh International Physiological Congress held in Edinburgh under the presidency of Sir Edward Sharpey Schafer, Professor of Physiology in the University, came to an end on Friday, July 27th.

#### INHIBITION, HYPNOSIS, AND SLEEP.

Professor I. P. PAVLOV (Petrograd), who was present at the Congress, had prepared a lecture on the identity of inhibition, as a constant factor in the waking state, with hypnosis and sleep, which was read for him by his son.

In some introductory paragraphs Professor Pavlov said that the highest nervous activity of the dog had been studied by himself and his numerous collaborators for the last twenty years, and that the investigation had always been conducted on a purely physiological basis; psychological conceptions or words were never used. The highest nervous activity consisted of analysis and synthesis of the external and inner worlds—of stimuli which reached the cerebral hemispheres from without and from within. The so-called reflexes or instincts, the latter being complex reflexes, formed the chief basis of nervous activity. Reflexes were the inborn connexion between definite outside agencies and corresponding definite activities of the organism. This reflex activity was the function of the lowest parts of the central nervous system. During life temporary connexions were formed under special conditions in the cerebral hemispheres. To the inborn reflexes he applied the term "unconditioned reflexes"; those individually acquired he called "conditioned reflexes." If some external stimulus was made repeatedly to coincide with some inborn reflex it acquired the powers of producing the same reaction as the unconditioned reflex. For example, food produced a food reaction; the animal performed certain movements with respect to the food, and saliva and gastric juice were secreted. If the feeding of the animal coincided several times with a certain sound then this sound, previously entirely indifferent, evoked the same food reaction as the food itself. The amount of saliva secreted was a measure of the intensity of the reaction. A similar principle applied to the formation of conditioned reflexes in the case of any other agent of the external world and in the case of other instincts—for instance, self-protection or the sexual instinct. The great synthesis between the outer world and the organism was accomplished in this way. A conditioned stimulus, if not accompanied by the unconditioned, was temporarily suspended; for instance, if in the example already given the sounds were not accompanied by feeding the food reaction it had produced would be lost, but after several minutes, or in some cases hours, it returned. It appeared, therefore, that there was an inhibition, but not destruction, of the reflex. Any stimulus, after it had become a conditioned stimulus, was generalized—that is to say, the conditioned reaction was provoked not only by the specially chosen stimulus, but by any other of the same type. After this introduction Professor Pavlov continued with the main subject of his address, as follows:

As a result of many preliminary guesses and tests we arrived at the following thesis: the inhibition already referred to, and ordinary sleep and hypnosis also, are one and the same process. Every conditioned stimulus, as soon as it is used alone, without being accompanied by an unconditioned one, sooner or later always leads to a drowsy state, or to sleep. Some conditioned stimuli produce sleep in a shorter time than others. In a similar way some animals develop this property more easily than others. As a general rule, sleep is induced the more quickly the longer

metabolic rate was depressed from the first, as evidenced by subnormal temperature, lethargy, and adiposity. The thyroid gland showed an extreme (?) compensatory hyperplasia during the first ten days; this was followed by permanent hypoplasia.

Feeding with anterior lobe caused both in dogs and cats a moderate (average 25 per cent.) acceleration of growth, as mathematically determined by radiography of the skeleton. The temperature of these animals had averaged slightly higher than that of controls. Administration of the anterior lobe raised the subnormal temperature and relieved the lethargy. It did not influence the failure in growth, nor had it altered the histological appearances of the degenerated epiphyseal cartilages. Injections of extracts of the anterior lobe raised the subnormal temperature of thyroidectomized animals just as thyroid extract did; this indicated a possible independent metabolic activator from the anterior lobe of the pituitary body.

Total excisions of the posterior lobe had given rise to no observable consequences. One animal so treated appeared perfectly normal eighteen months after the operation and had two normal pregnancies and parturitions. Mechanical stimulation of the posterior lobe by operative manipulations had caused an extreme, evanescent polyuria. The polyuria following continued irritation by the contact of a platinum plate was still greater and of longer duration. The operations were conducted with care, and no interpeduncular cerebral lesion could be found *post mortem* by microscopical examination. The conclusion drawn was that the anterior lobe exerted an influence (probably independently of the thyroid) on the activity of the cells of the entire organism, and a special "trophic influence" upon cells of an embryonic type, such as were found in germinal epithelium in both the young and mature, and in the epiphyseal cartilages of the adolescent. In spite of the well known physiological effects of posterior lobe extract, extirpation of this portion of the organ gave no indication of its physiological action in terms of the consequences of its deficiency.

#### *Circulation in the Spleen.*

Mr. J. BARCROFT (Cambridge) gave a demonstration upon the circulation in the spleen, showing how small was the quantity of carboxyhaemoglobin in the spleen of an animal which had breathed CO. If rats were placed in 0.1 per cent. CO, the blood in the general circulation became saturated up to 50 per cent. in twenty-four minutes, and blood taken from the liver was indistinguishable from that in the general circulation; but the haemoglobin in the spleen required at least another twenty-five minutes to become saturated to the same extent. Conversely, if rats had been in 0.1 per cent. CO till the haemoglobin of their blood and the haemoglobin of their spleen pulp were saturated to over 60 per cent. saturation, and were then exposed to ordinary air, the blood would in forty-five minutes be only 30 per cent. saturated, whilst another hour elapsed before the haemoglobin of the spleen reached that figure. It appeared, therefore, that the spleen pulp contained large numbers of corpuscles which were not circulating in the ordinary sense, and was, in fact, a sort of backwater in the circulation.

#### *Phagocytic Cells of the Omentum.*

Drs. J. C. ARMOUR and JOHN TAIT (Toronto), in a communication on phagocytosis by the omentum, said that, as was originally shown by Buxton and Torrey in 1906, there are clusters of phagocytic cells in the omentum of the rabbit and guinea-pig—the so-called "taches laiteuses" of Ranvier. By intraperitoneal injections of Indian ink the distribution and arrangement of the phagocytic cells of the omentum of the cat, dog, rabbit, guinea-pig, woodchuck, squirrel, chipmunk, rat, mouse, and bat had been examined, and it had been found that each kind of animal had its own characteristic and distinctive arrangement of phagocytic cell groups. In the dog, cat, and rabbit the arrangement in the adult was different from that in the newly born. As a rule the phagocytic cells were in clumps or clusters, which might or might not have a special blood supply. Individual phagocytic cells also occurred in the ground substance of the omentum. It was by means of these adhesive phagocytic cell clusters that the omentum attached itself to or

wrapped itself around foreign bodies. Tubercle bacilli introduced into the peritoneum became ingested by omental phagocytic cells.

#### *Pernicious Anaemia.*

Drs. A. V. SZENT-GYÖRGYI and R. BRINKMAN (Groningen) gave a demonstration on the pathogenesis of pernicious anaemia showing that the haemolytic substances which could be extracted from normal blood consisted of higher fatty acids. In plasma these were inactivated as calcium compounds, but the calcium salts of the higher unsaturated fatty acids preserved their capillary action and were haemolytic. Injection of small amounts of linolenic acid in the rabbit caused a severe haemolytic anaemia. The fraction of higher unsaturated fatty acids was in normal blood very small; in pernicious anaemia it was distinctly increased.

#### *Action of the Diaphragm.*

Drs. J. M. W. MORISON and B. A. McSWINEY (Manchester) read a communication upon the action of the diaphragm in relation to movements of the chest wall. Their investigations were carried out on normal subjects and patients with unilateral paralysis of the diaphragm, congenital and acquired, in order to compare the action of the diaphragm with the movements of the chest wall. X-ray examination in cases of unilateral paralysis showed reversed action of the diaphragm on the paralysed side. The movements of the chest wall were recorded by means of a respiratory waistcoat. No movements were observed in the lower part of the chest wall on the affected side. In the upper region there was diminished movement, but otherwise no abnormal change.

## England and Wales.

### THE GENERAL INFIRMARY AT LEEDS.

THE scheme for the redistribution of beds and cots throughout the Leeds General Infirmary which was adopted some time ago has not had full expression until the recent opening of the remaining large ward for the accommodation of children. Old students of the Infirmary will remember the wards numbered 6, 8, and 10 which form the upper story of the three back pavilions. These have recently been connected by balconies at their northern ends, and in this way an emergency exit is provided in case of fire as well as excellent accommodation for the open-air treatment of the children in suitable weather. Each ward has accommodation for 33 cots. One ward is for medical cases. Surgical cases absorb one ward and 19 cots in another, and the remaining 14 cots are divided between the ophthalmic and aural departments. Between wards 6 and 8 is situated the newly opened Princess Mary ward for infants which can be approached from the square of No. 8 ward as well as from the terrace. There has thus been accomplished what has been aimed at for some years, namely, the provision of "A complete children's hospital within the walls of the General Infirmary" by the segregation of the children and by the extension and improvement of the accommodation for them.

Without further extension the Infirmary is now working to the limit of its capacity. Including a few emergency beds and cots there are now 432 beds for adults, and 112 cots for children. But in a large hospital things must never stand still and there are schemes for the enlargement of the nurses' home, for the development of the instructional block for the students and for the possible formation of a great receiving room department, which it is believed will greatly improve the out-patient department, and make the general working of the Infirmary smoother and more efficient. The large and progressive dental school has its clinical department within the walls of the Infirmary, for the large hall which was used as a waiting room for the out-patient department before the recent extensions, has been modified to meet the requirements of the dental school, which also has the use of a portion of the old operating department. The time will come, and it is hoped that it will come soon, when a fully equipped dental hospital will be built in close rela-

stomach, but when it forms a tight constriction the same mechanical effect is seen as in pyloric obstruction. The effect of regurgitation is not felt in the proximal sac. No typical fall in the acid curve due to neutralization is seen; the total chloride and acid curves maintain their heights and the inorganic chloride curve remains low. The delayed emptying of the proximal sac may lead to hypersecretion. (Fig. 6.)

The effects of stricture at the outlet or in the body of the stomach are therefore purely mechanical; the emptying of the stomach is delayed and neutralization is prevented.

to hypersecretion. (Fig. 6.) The effects of stricture at the outlet or in the body of the stomach are therefore purely mechanical; the emptying of the stomach is delayed and hypersecretion set up, whilst neutralization is prevented.

3. Absence of gastric juice—achylia gastrica.

The rise occurs in the normal fashion, and is accompanied by a corresponding rise in the inorganic chloride curve. The protein HCl curve is below the inorganic curve, but the two may cross as in normal cases. Free HCl is absent. Normal amounts of fluid are extracted. (Fig. 7.) The causes of this excessive neutralization is to be found in increased duodenal neutralization of the pylorus being hypotonic. A definite relaxation does not usually occur at a given point, but excessive relaxation appeared commonly found atonic with diminished peristalsis.

secreted, as determined by the total chloride curve standing at 60 or below while the stomach contains food; otherwise the curves are like the normal, but lower, and free HCl may be present or absent. (Fig. 9.) If the diminution be considerable, curves indicating excessive neutralization appear, as a normal duodenal regulation will produce this effect. The total chloride curve stands below 60 when the stomach contains food and the amounts extracted are small. The total and inorganic chloride curves in this case rise very slowly to the end; the protein HCl curve is similar and the lowest of the three. Free HCl is absent. (Fig. 10.) In cases of dyspepsia with absence of free HCl the gastric glands may sometimes be stimulated into increased activity by giving a meat meal.

Gastric Acidity following Gastro-enterostomy and

*United Operations.*

1909. Two types of curves are recognized: (1) a successful gastro-intestostomy practically complete neutralization occurs. This is shown by the height of the total chloride and inorganic curves. Except for a slight rise in the beginning of digestion the HCl curve is zero. (Fig. 13.)

Gastro-entostomy, therefore, relieves the patient not only by facilitating the emptying of the stomach in pyloric obstruction, but also by allowing free reorganization of intestinal contents, thereby neutralizing the HCl in the stomach, as Paterson has maintained since 1909. Excision of the pylorus will probably prove eventually to be the better operation for this reason.

### Hyperscretion of Gastric Juice.

A general consensus of opinion has not yet been arrived at with regard to what actually constitutes dispersion. It is generally assumed that if it is an anonymous distribution (that is, if it is a *breakeven*) above the normal distribution, it is extracted, a nonanonymous dispersion is present. The point in dispute is what amount should be regarded as the normal.

The deputation was introduced to the Minister by Professor M. Hayes, T.D., National University (Speaker in the Dail); Sir James Craig, M.D., T.D. (Dublin University), sent a message expressing his regret that he was unable to be present owing to his absence from home on a holiday. The main object of the deputation was to make certain representations to the Minister of Local Government with regard to the announcement that a Public Health Bill was to be brought forward in the Dail at an early date.

#### *Statement by the Deputation.*

Dr. Rowlette, speaking on behalf of the deputation, said that it was understood that the Local Government Department had been at work on a draft for a Public Health Bill, but the Irish Medical Committee had no knowledge of what it might contain. Their view was that no measure would be adequate unless it was thorough-going. The need for thorough and thoughtful attention to public health must be admitted, and the Irish Medical Committee was of opinion that no activity of Government, maintenance of law, development of industry, and defence against enemies, was more essential to the welfare of the nation than the care of the public health. The condition in Ireland gave cause for anxiety. The death rate in other civilized countries had fallen greatly in the past sixty years; in Ireland it had been practically stationary. The mortality from tuberculosis had fallen in Great Britain by a half, in Ireland by only a third. Infant mortality in Ireland as a whole was not high—a fact observed in all pastoral countries. But in the cities of Ireland it was alarmingly high, and Dublin had the highest infant mortality in the British Isles—134 per 1,000 as compared with 80 per 1,000 in London. Less care was paid to public health in Ireland than in any civilized country. In other countries every city and county and every considerable town had its expert whose entire duty was to safeguard the health of the people. In the whole of the Free State there was only one whole-time medical officer of health; the officer for Dublin. In country districts sanitary work, in the modern sense, hardly existed. The dispensary doctor was medical officer of health for his district as well as dispensary doctor. For the duties of this added office he was paid a separate salary, which varied from £5 a year to £30. The salary was, no doubt, fixed contemptuously to emphasize the fact that the authorities did not wish that the duties should be taken seriously. As the dispensary doctor had to make his living as a private practitioner in dependence on the people who were most likely to offend against the sanitary laws, it was clear that a rigorous attention to preventive work was impossible.

The deputation wished to urge the Minister to adopt in its entirety the programme of the Irish Public Health Council which had been accepted by the medical profession, welcomed by the press, and recently had, in its essentials, been put forward by the General Council of County Councils, a body thoroughly representative of the ratepayers of the country. The central features of the programme were the establishment of a Ministry of Health and of a National Medical Service. The mere naming of a ministry as "Ministry of Health" would impress on the Minister and on his staff the predominant importance of their duties regarding health. At present there was nothing to suggest that, among the multifarious activities which came under the supervision of the Ministry of Local Government, health was more important than the care of roads or the control of markets.

The establishment of a national medical service had been recommended in 1906 by the Vice-Regal Commission on Poor Law Reform; it had subsequently received the approval of the medical profession by a plebiscite; the Commission to consider the extension of medical benefits to Ireland, in 1913, advocated it; the Irish Public Health Council, in 1920, discussed the alternative proposal for a county medical service, and unanimously reported in favour of a National Medical Service. The proposal was recently adopted by the General Council of County Councils. The Irish Medical Committee saw no hope of making the public medical services attractive to the best class of young Irish medical men and women by any other means than by the establishment of a National Medical Service.

The profession had welcomed the reforms made during the past few years both by the first Dail and recently on the proposals of the Minister. They were in the right direction but they did not go far enough. The making the county the health unit was a great advance. In one particular, however, they went too far—in the abolition of district hospitals. While the principle of centralization in one hospital in each county was good, there was danger in applying it too rigorously. Patients were averse to travelling too far from their homes, and in many cases of illness the long journey added a great risk. The

result was that many patients refused to go to hospital and had to be treated in unsuitable conditions. The Irish Medical Committee did not know whether the Minister had considered the advisability of setting up a body such as the Irish Public Health Council had been, or a health council such as was recommended in the report of the Irish Public Health Council, but thought such a body would be helpful to him.

The Minister of Local Government, in reply, stated that it was his intention to introduce immediately a Public Health Bill but, in view of the early dissolution of the Dail and the general election within the next two weeks, it would be impossible for him to adhere to his programme. He, however, hoped that it would be one of the first measures to be introduced in the Dail after the election. He fully realized the unsatisfactory condition in the Free State of questions relating to public health and the public medical services. It was his intention to have dealt with public health before undertaking the reform of the medical services. He proposed that a county medical officer of health should be appointed to look after each county in the Free State and under him there would be school medical inspectors and tuberculosis medical officers. He hoped that such salaries would be paid as would attract the best young doctors in the profession in Ireland. He did not favour the establishment of a Ministry of Health apart from local government; it was only a difference in nomenclature which in practice meant very little. He favoured the formation of an advisory body similar in functions to the existing Irish Public Health Council. The Minister regretted that owing to an urgent meeting of the Cabinet to which he was summoned he could not wait to discuss many other medical matters with the deputation, but suggested that the deputation should continue the discussion with Mr. McCarron, Secretary of Local Government, and Dr. E. F. Stephenson, Medical Administrator, who were present.

#### *Further Discussion.*

Mr. O'Maille, T.D., spoke of the case of doctors in county Galway, especially those in the Connemara district, and protested against the action of the Local Government Department in refusing to sanction the full amount of £300 per annum for the dispensary doctors. Dr. Casey and Dr. Greene, who practise in Connemara, stated that their districts were twenty miles in length and fifteen miles in breadth. Dr. Greene said that the population of his district was over 8,000 and 80 per cent. were treated gratuitously under the Medical Charities Acts. Owing to the inadequacy of his salary he was unable to give sufficient attendance to the sick in his district, as if he were to do so he would have to be paid more than double his present remuneration to cover the travelling expenses. The refusal of the Local Government Department to approve the full amount of the increased salaries passed by the Kinsale Board of Guardians was also the subject of a warm discussion, the deputation pointing out that it was impossible for the doctors in these districts to give an adequate medical service in the circumstances. The deputation brought to the notice also the unsatisfactory conditions of holidays for medical officers in certain counties where unsympathetic local authorities nullified the holiday regulations granting an annual holiday not exceeding one month. Owing to the faulty wording of that regulation it was open to a local authority to give only a few days' holiday and to fix the remuneration at such a low weekly rate that no substitute could be found to accept it. Dr. Stephenson stated, on behalf of the Local Government Department, that such action would be impossible in the future as the revised regulations provided that the doctor going on leave should be allowed a full month's holidays, and that a sufficient remuneration for the substitute would be mandatory on the local authority. The Department, however, would not undertake to go further than treating each case of refusal, in any respect, as it occurred, but promised to act promptly so that the doctor going on leave might take his holidays at the time arranged to suit him, and to urge upon the local authorities to appoint as locum tenens, so far as practicable, the substitute nominated by the doctor going on leave. The question of local authorities including illegal conditions of service in the advertisements for medical vaccines, was also discussed and the deputation suggested that, in accordance with the regulations, notice of each medical vacancy and the terms of the advertisement therefor should be submitted to the Local Government. This suggestion was agreed to. Other matters having been considered the deputation thanked the Local Government officials for their patient hearing of the different questions brought to their notice.

MESSRS. LONGMANS, GREEN AND CO. announce that the new edition of Sir Edward Thorpe's *Dictionary of Applied Chemistry* will extend to seven volumes, a great part of the last volume being devoted to a complete index of the work.

gastrogenous diarrhoea, only a few cubic centimetres of mucoid juice like white of eggs might be obtained. The presence of blood in leucocytes in chronic gastritis, and food debris in pyloric obstruction, afforded further useful information. The rate of emptying might be very inaccurately ascertained by the fractional method, and was closely comparable with the rate of emptying as estimated radiographically. The amount of the supernatant fluid and the regravitation of bile in subsequent specimens were further simple macroscopic observations of contributory importance. The fractional test meal could really be regarded as a diagnostic test in one condition, and that was pyloric obstruction. In this condition it might give definite evidence as to the cause of the obstruction. Nevertheless as a gastric efficiency test it was of distinct value in duodenal ulcer, Addison's anaemia, and chronic gastrogenous diarrhoea. In other cases of dyspepsia, due to disease of the gall bladder and appendix, hyperchlorhydria and achlorhydria both occurred more frequently than in normal series, and probably depended respectively on reflex pyloric hypertonus and chronic infection in the upper gastro-intestinal tract. It should be clearly understood that the fractional test meal was a rough test and that it could only be regarded as accessory to careful clinical investigations. With these provisos it was a test of real utility.

Dr. Izod Bennett made remarks which are embodied in the paper printed below.

Dr. H. C. BULL said that the researches of Gorham and of Paul White had somewhat altered opinions as to the value of the interpretations put upon fractional test meals. These independent observers obtained similar curves by giving a test meal and withdrawing the meal fifteen minutes later in 10 c.cm. samples, the whole operation occupying only twenty minutes. Their work supported the conclusion that the tube only gave information of the area of the stomach in which it lay, and therefore, as symptoms of cancer, in which the pathological change was very great, were most insidious in their onset, whereas the stomach emptied, the acidity apparently rose. The fractional method gave very little help, while in the organic diseases the percentage of error was very high. On the other hand, where there was organic disease, the x ray was reliable in over 50 per cent. of cases, and in certain of the reflex disorders also great accuracy of diagnosis could be obtained. At the present time it seemed that the fractional tube was a valuable aid in research, and in the hands of Drs. Rehnus, Kyle, and Bennett in this country, and Drs. Rehnus, Lyon, and others in America, would shed more and more light on the obscure disorders of the stomach; as a clinical aid its usefulness was limited.

Dr. MacKenzie was glad to find emphasis laid on what might be called macroscopic gastric tests, such as the residue, occult blood, aspect, smell, consistency, and so on. Too great a price would be paid for modern clinical laboratory tests if the common special sense education were lost. This should go hand-in-hand with the advanced methods described by Dr. Bolton. The ability to distinguish between the achlorhydria of pernicious anaemia and carcinoma of the stomach was striking, but of little practical value. Could a distinction be made in the large group of non-malignant cases (gastritis, neurasthenia, and so on) that have no free acid? The method of ascertaining the rapidity with which the stomach emptied by the combined use of x rays and fractional test meals was, he believed, very valuable.

Dr. MacKenzie Wallis (London) said that so far the discussion had been confined to the use of the fractional method of gastric analysis. The detection of occult blood in the stools had, in his own experience, proved a most valuable individual test as an aid to diagnosis of carcinoma of the stomach. The scheme of investigation he had carried out for some time was as follows: The patient was

Dr. HUGH MACKENZIE thought that previous speakers had overestimated the value of x rays in diagnosis of stomach diseases, for in his experience radiographic examination had often failed to throw any light on obscure cases. He asked whether in pernicious anaemia the secretory changes which often preceded the anaemia were to be regarded in any way as contributing causes to the disease itself. His experience led him to think that surgeons overestimated the frequency with which cancer followed ulceration of the stomach.

Reply.

Dr. BOLTON, in his reply, emphasized the fact that pathological findings must be co-ordinated with clinical observations in order to arrive at a correct diagnosis. He pointed out that the object of research was to investigate the course of disease, and only secondarily to supply tests by means of which disease could be diagnosed. In reply to comments made by contributors to the discussion, he remarked that in pernicious anaemia the secretory disturbances were not necessarily the results of the anaemia, for in some cases the disease might exist in a most pronounced form without any disturbance of gastric secretion. With regard to the frequency with which cancer followed gastric ulcer, he declared that he thought that a generous estimate would be that cancer followed in 7 to 8 per cent. of the cases. The occult blood test was a valuable aid to diagnosis of cancer and ulcer of the stomach, and there was, as a rule, insufficient blood in the stools of a patient with chronic gastritis to give a positive test. In reply to the criticism that the specimens withdrawn by the fractional test method were not fair samples, he reminded his audience that the churning action of the stomach movements must ensure thorough mixing. He agreed that if the stomach was washed out free HCl would be found in the contents of a carcinoma stomach. The difficulty with regard to the ordinary test meal was to determine the right moment to withdraw the fluid to be tested; it did not arise in analysis by the fractional method, which had already been very useful in the study of gastric diseases; further research would undoubtedly extend the sphere of its utility.

## THE EARLY DIAGNOSIS OF CANCER OF THE STOMACH BY MEANS OF GASTRIC ANALYSIS.

T. IZOD BENNETT, M.D., M.R.C.P.,

Assistant Physician, and Assistant to the Professor of Physiology, Middlesex Hospital; Beit Memorial Fellow for Medical Research.

During the past three years I have had the opportunity of performing gastric analysis, by the fractional method, on some three hundred cases, including diseases of many types, at the Middlesex Hospital.

As is always the case when a new method of investigation is introduced, fractional gastric analysis has encountered severe criticism, chiefly at the hands of those experienced in older methods. These criticisms depend chiefly on the fact that the gastric contents are not homogeneous, and if a small sample be removed and analysed it cannot be expected accurately to represent the contents of the stomach. A contribution to the discussion on diseases of the stomach in the

cancer should be left unexplored, and this could best be done through the health departments of the various local authorities under the guidance of the Minister. We are so utterly ignorant of the causes and sources of cancer that we never know at what moment or from what direction illuminating knowledge may arrive.—I am, etc.,

Blackpool, Aug. 1st.

LEONARD MOLLOY.

#### CONGENITAL HYPERTROPHY OF THE PYLORUS.

SIR,—I have read with the greatest interest Dr. G. F. Still's instructive account of his experience in the treatment of congenital hypertrophy of the pylorus, which appeared in your issue of April 7th. To me, Dr. Still's apology for broaching a subject about which so much has been written in recent years seemed quite unnecessary, as it is most important to stress the high proportion of cures which can be brought about by early operation in a condition so easy to diagnose. Such diagnosis is only easy, however, when the existence of the condition is realized and search made for its distinctive signs.

It is a surprise to me to notice the low proportion of recoveries after the Rammstedt operation in Dr. Still's series. In the last three years I have performed this operation, which I first saw done by Mr. Tyrrell Gray at Great Ormond Street, in eighteen cases with two deaths. Of these, fifteen were cases at the Children's Hospital, Melbourne. This series is small compared with those of some American surgeons whose mortality rate is lower than mine, but I see no reason why, with further experience, especially as regards earlier diagnosis, these results should not be improved. Notwithstanding the extraordinarily good results of forcible dilatation in Dr. Still's private cases, it would appear that the simple muscle division of the Rammstedt operation, which can be carried out comfortably in ten to fifteen minutes, is more suitable for general use than the modified Loreta's operation, which theoretically is more severe, but of which I have had no experience.

On this point I should like to have the benefit of Dr. Still's large experience. Has he noticed any indications which would lead him to advise the Rammstedt or Loreta method of operation in individual cases, or does the choice entirely depend on the preference of the surgeon?

To my mind, speed is essential to a successful result, especially since delayed diagnosis is so often responsible for exhausted patients. Even more important is warmth during and after operation; a hot bed in which the heating is by electric light bulbs is very satisfactory. Such details as these make all the difference in an enfeebled baby.—I am, etc.,

Melbourne, June 10th.

RUPERT M. DOWNES.

#### MEDICAL CHARITIES.

SIR,—The question put by Dr. Macdonald, the well deserved reflection on the scant support accorded by the profession made by Dr. Dearden, and the reply by the Treasurer at the Annual Meeting will, I hope, bring home to the profession the needs of the Royal Medical Benevolent Fund.

Dr. Haslip's remarks call for some reply, and especially for information as to the efforts that are being made by the Committee of Management to increase the income of the Fund. Dr. Haslip is (as he stated) a member of this Committee and as such has a voice in the management. It is a matter of regret that owing to his many engagements and his recent illness he has not been able to attend as often as we could wish.

The Medical Agency, of which Dr. Haslip is chairman, has contributed most handsomely to the Fund. These gifts have been acknowledged with gratitude not only by the Committee of Management and in the medical press, but by special letters from the Treasurer.

The subscriptions collected through the medium of the Association amounted last year to £800. Moreover, through the kindness of the Editor of the *Lancet* and the Editor of the *British Medical Journal* a summary of grants is published monthly. Those who read their journals cannot but be informed of the existence and the needs of the Fund.

The conference to which Dr. Haslip refers took place in 1922 at the request of the officials of the British Medical Association, and was attended by representatives of Epsom College and of the Royal Medical Benevolent Fund. Dr. Haslip proposed that the two bodies should be amalgamated and that there should be a central bureau for the collection of subscriptions. This proposal did not meet with the approval of either body, as it involved the abandonment of organizations, metropolitan and provincial, for the collection of funds that had been built up by years of patient endeavour, without any sufficient assurance of their adequate replacement; and in the case of Epsom College there was the additional objection that such action would tend to restore to the college as a whole, which is a general public school of the ordinary type, a charitable aspect that had been proven to be harmful to the College, as well as to the Medical Foundation incorporate in it, and which some thirty years ago was an important factor in inducing the Council of Epsom College to obtain an amending Act of Parliament. It was felt also that the aims of Epsom College and the Royal Medical Benevolent Fund were essentially distinct, in that the former existed primarily for educational, the latter exclusively for charitable, purposes.

Seeing that so far as the Fund was concerned some 20,000 members of the profession do not belong to the British Medical Association, it was considered wiser to remain free to appeal from one centre to the profession as a whole. This proposal would, moreover, entirely disorganize the present system of collecting subscriptions through local secretaries, which adds a personal and sympathetic touch of no little value.

Dr. Haslip's effort in the cause of education and of charity was cordially appreciated by both bodies, and I hope will not be lost upon the profession.

That the executive have not been idle in developing new ideas and methods during the last few years the following brief account will indicate, and will go some way, I hope, to remove the impression of apathy conveyed in Dr. Haslip's remarks. It is an error into which he could not have fallen had he been in closer touch with the management.

During the last two years special appeals have been issued in the following districts: Bath, Birmingham, Bolton, Bristol, Bromley, Birkenhead, Bury, Cambridge, Cornwall, South Wales and Monmouthshire, Surrey, Devonshire, Bootle, Manchester, Portsmouth, Buxton, Burnley, Weybridge, Watford, Sutton, Enfield, Blackburn, Altrincham, and similar appeals are being prepared for other towns this autumn.

Realizing that printed matter is often thrown in the waste-paper basket unread, the various local secretaries have been asked to write out an appeal, which has been reproduced. A stamped envelope is addressed to every non-subscriber and sent to the local secretary, who completes the letter by inserting the name. The reply is returned to the office or the local secretary, as the latter desires. In some cases an addressed stamped envelope is enclosed for reply. Up to the time of writing over £400 in new subscriptions, largely in banker's orders, have been received this year, and replies are still coming in. Not only have these undertakings been initiated by the honorary secretary, Dr. Newton Pitt, but owing to the illness of the secretary the bulk of the work has fallen upon him. The festival dinner in 1913, at which £3,197 was raised, at least informed the profession, the entire body being circularized of the existence and needs of the Fund.

Taking the last two decennial periods, the income from investments and subscriptions mounted in 1902 to £3,946, in 1912 to £6,222, and in 1922 to £8,080. The amounts distributed were respectively £3,795, £5,497, £8,397. The number of grantees has increased from 140 in 1902 to 304 in 1922, and annuitants from 140 to 163. The progress of the Guild, a branch of the Fund, is shown by the increase in income from £1,725 in 1912 to £2,536 in 1922. The progressive character and successful results of the Guild's work are well known. Notwithstanding all that is being done the income is far below what is needed, and it must, I fear, be recognized that the lack of support is

Grand harm has, I believe, been done by endeavours to interpret results of gastric analysis on empirical or purely chemical grounds. I am not aware that anyone has yet been able to demonstrate any specific chemical substance secreted by readily accessible tumours such as malignant growths of the breast or tongue; certainly no such specific substance has been discovered in the blood, and yet one still encounters attempts to found diagnostic tests for cancer of the stomach on the presence of some unusual substance in the gastric contents being supposedly a product of the actual tumour. I would repeat my belief that these substances are effects of the tumour only in so far that gastric neoplasms produce partial or complete gastric obstructions. The detection of early cancer of the stomach becomes possible if steps are taken to make stagnation easily demonstrable; this can be done by giving some finely divided charcoal in milk overnight—two teaspoonsful in a tumbler of milk is sufficient, but it is perhaps well to give a charcoal biscuit in addition. The next step is to evacuate the fasting stomach content with great care; Keffus has shown that this can be done far more securely with one of the small modern tubes than with the large ones formerly employed.

In a total series of 55 cases in which the clinical diagnosis of gastric carcinoma was definitely made, charcoal was visible in the fasting content next morning in 50; but other signs of stagnation—a foul odour, lactic acid, and a relatively high concentration of acids other than hydrochloric—were present in 20 out of the remaining 23 cases. Blood was present, either fresh or partially broken up, in 35 cases.

### A Summary of Proven Cases.

Under existing conditions it is difficult to secure accurate notes of the after-history of many hospital cases, and for this reason I am unable to describe all the cases referred to as proven cases of malignant disease. In 20 cases laparotomy, or a full history of the case, allows me to speak with certainty, and analysis of these is not without interest. They are divisible into three groups.

#### Group 1: Cases with Pyloric Obstruction.—Nine cases fall within this group: in 4 of them free HCl was present in the fasting stomach content as well as after the test meal, in 3 it was present only after the meal, and in 2 it was absent throughout. In all these cases the diagnosis was evident from the test meal; in 5 it was made independently by the radiograph; in 4 the x-ray report merely recorded gastric stasis or gastric atony. All were operated on, and it is significant that in 5 of the 9 gastrectomy was performed without difficulty and no metastases were visible. In 3 of these requirements were visible.

gastro-enterostomy, with considerable immediate relief. A typical gastric analysis chart from a case in this group is shown in Fig. 2; it illustrates the relatively high total acidity compared with the low free HCl, the tendency to haemorrhage, and the marked delay in gastric emptying. All of these are characteristic of the group; haemorrhage is not infrequently absent, but the picture of partial obstruction is typical of itself.

Group 2: Cases without Pyloric Obstruction but with Signs of some Stagnation.—Nine cases fall in this group also; in 5 there was free HCl in the fasting stomach, in 4 there was not. The picture of partial obstruction is typical of itself.

I believe, been done by endeavours to interpret results of gastric analysis on empirical or purely chemical grounds. I am not aware that anyone has yet been able to demonstrate any specific chemical substance secreted by readily accessible tumours such as malignant growths of the breast or tongue; certainly no such specific substance has been discovered in the blood, and yet one still encounters attempts to found diagnostic tests for cancer of the stomach on the presence of some unusual substance in the gastric contents being supposedly a product of the actual tumour.

In none of them was there any delay in the emptying time after a meal, and in several the stomach emptied very rapidly. This may be due to several causes—in some cases there is an invasion of the pyloric region with neoplastic tissue which seems to prevent closure, and in others the tumour in the body of the stomach appears to stimulate peristalsis and cause rapid emptying. The cases secreting HCl give a picture which is at first sight one of normal secretion—an example is given in Fig. 3, but it too, there is a relatively high proportion of organic acid, as opposed to free HCl in the fasting stomach content, and this, together with its characteristic odour, traces of charcoal, and sometimes obvious blood, makes diagnosis easy. Cases with complete achylorrhia were similar to that illustrated in Fig. 1. This group differs from Group 1 in that surgical interference was seldom indicated. In the majority of cases a palpable tumour made it clear that the possibility of excision was remote. Only two were operated on; in at least two others marked temporary amelioration of symptoms was obtained by deep x-ray therapy.

Fig. 3.—Fractional gastric analysis, carcinoma. The high total acidity with charcoal vomiting. The high total acidity with charcoal vomiting. The high total acidity with charcoal vomiting.

The cases I have detailed are selected only in so far that they are the proven ones amongst a much larger number: in some 50 others the diagnosis was clinically definite, but I have excluded them on account of their anal history being unknown. As far as I know I have not seen a case of malignant disease of the stomach which did not give a positive diagnostic picture on gastric analysis, and the only condition with which this can be confused is that of gastric syphilis. In syphilis of the stomach there may be tumour formation with pyloric obstruction which is indistinguishable from cancer by any means save histological examination; the Wassermann reaction is positive in such cases, but we have at present no means of knowing whether this may not be a sign of old infection with concurrent malignant disease.

I have already commented on the fact that the incomplete descriptions of the textbooks do not necessarily represent the opinion of those with a special personal experience of gastric analysis. An example of the latter type of opinion may be found in the recent paper by Donald Hunter; his findings agree substantially with my own, the less definite picture which he obtained being accounted for by the fact that he did not give such extensive gastric lavage in the malignant cases. A. F. Hurst has also, in recent communications, drawn attention to the relative frequency of free HCl in these cases when examined by the fractional method.

Gastric analysis should be regarded as a clinical and not as a laboratory procedure; it is to be recognized, and if the observer would seek for the evidence I have outlined, the early diagnosis of cancer of the stomach would be enormously improved, and the percentage of operable cases notably increased.

In conclusion I would express my indebtedness to my colleagues at the Middlesex Hospital and its medical school for the facilities they have afforded me in this work. The expenses incurred in performing it have been partially defrayed by a Government grant made on the recommendation of the Royal Society.

or phosphorus or both. The latter are called the phosphatides, and are soluble in, or extracted from, organs and tissues by ether and alcohol. The term lipin as defined by Professor Maclean, including the phosphatides, are "substances of a fat-like nature yielding on hydrolysis fatty acids or derivatives of fatty acids and containing in their molecule either nitrogen or nitrogen and phosphorus." Generally speaking, the phosphatides are soluble in the majority of ordinary solvents for fat with the exception of acetone, in which they are practically insoluble. Professor Dreyer repeats and emphasizes that "it was by no means intended to imply that all fatty and lipoidal substances present in the micro-organisms had been removed. Only some of the lipoidal substances are taken away in this mode of preparation by washing with acetone after formalin treatment." This view accords, therefore, with the above-mentioned fact that acetone does not extract this group of substances. The acid-fast properties are usually attributed to the waxy substances which, however desirable to remove *in vitro*, are not included in the lipoid, phosphatide or lipin group of substances.

In the interesting description of Dr. David Thomson's method of defatting bacilli the conclusion is that lipoids are not of much antigenic value. For this reason he practically uses the protein fraction. He notes, however, the work of others who claim antigenic properties for the lipoids and the waxes.

It may be useful to workers in this field to point out a third method to which I have drawn attention and employed in dealing with the tubercle bacillus. It is preliminary to digest or split the fats and lipoids of killed tubercle bacilli by lipase—the natural fat and lipoid-splitting agent. In this way saponified extracts were prepared and indicated for therapeutic use. Preparations were made also by extracting tuberculous material with the usual fat and lipid solvents (alcohol, ether and chloroform) successively in the cold, or in a Soxhlet's apparatus in the usual way, and after evaporation saponifying or emulsifying the extracted material.

The method in the main differs from others in that the products of the fats and lipoids are utilized, together with the proteins, phosphates and other constituents or derivatives of the bacillus. By means of ether the fatty acids and protein fraction can be separated and thus used either together or separately.

I have preferred to adopt the current nomenclature, namely "activators" or "co-enzymes" of lipase rather than "antigens" because the former more correctly indicate the part played by these and allied substances after injection in the stimulation of lipolytic activity in the blood and tissues, and thus attacking the fats and lipoids of the bacillus in the infected organism.

I have been using the same method of preparation in dealing with the fats and lipoids of the cancer cell and tissues. In this case acid-meta-proteins (hydrochloric and acetic acid) preparations have been made and used also, on the basis that similar preparations from normal tissues were found in my former experiments to markedly act as stimulants of lipolytic activity in the blood and tissues.—I am, etc.,

J. A. SHAW-MACKENZIE, M.D.Lond.

London, July 16th.

AN association for the study of hay fever, asthma, and allergic diseases, limited to 100 members, has been formed, with Dr. Grant L. Selfridge, of San Francisco, as president.

THE number of cases of small-pox notified in Germany during 1922 was 215, as compared with 688 in 1921 and 2,042 in 1920. Most of the cases during these years occurred in the Oppeln district in Upper Silesia. In 1922 an epidemic of 135 cases was apparently caused by the burial of a child from Poland who had died of small-pox and by a newspaper carrier continuing his occupation while suffering from the disease.

A NATIONAL Congress of Physical Education will be held at Bordeaux from September 24th to 26th, under the presidency of Professor Sigalas, Dean of the Bordeaux Faculty of Medicine. The work of the Congress will be divided into three sections: (1) Physiology, circulation and respiration during exercise; (2) physical education, the dosage of exercise for the child; (3) choice of sports according to age.

## Obituary.

WILLIAM FORD ROBERTSON, M.D.,

Pathologist to the Scottish Asylums.

By the untimely death of Dr. William Ford Robertson, cut off by illness in his 56th year, in the midst of his all-absorbing and invaluable researches and his illuminating and highly important discoveries, Scotland has lost one of her most gifted and devoted workers in the field of pathology and medicine, and the world has been deprived of one who throughout his life was predominantly imbued and impelled both by an altruistic desire to do something to alleviate pain and suffering, and by the true spirit of research, the pursuit of truth for its own sake.

He was born on July 28th, 1867, at the farm of Nottylees, on the south bank of the Tweed, but just within the Scottish border. His father died in 1870, and the son, after a short period at Eskbank Academy, went to George Watson's College, Edinburgh where he received his main school education. Afterwards he had two years' business training in a lawyer's office, and then entered as a medical student at the University of Edinburgh. During the later years of his undergraduate course he undertook to do extra work in the pathological department of the Edinburgh Royal Infirmary, which was then under the charge of Dr. William Russell, now Emeritus Professor of Clinical Medicine; here he displayed his innate powers of enthusiasm, originality, and manipulative dexterity. Certain improvements which he devised in histological methods were deemed worthy of publication in the *Journal of Anatomy and Physiology*—an exceptional distinction for an undergraduate. He graduated M.B., C.M. Edinburgh in 1891; afterwards he held the appointment of house-physician at the Edinburgh Royal Infirmary under the late Dr. Wyllie, and at the Royal Hospital for Sick Children, Edinburgh, under Dr. T. M. Burn-Murdoch. After a short experience of general practice he determined to devote himself to medical research as a speciality and end in itself and not merely as a stepping-stone to some senior hospital or university appointment, and Sir Thomas (then Dr.) Clouston secured his services as pathologist to the Royal Edinburgh Asylum in succession to the late Dr. James Middlemass, who in 1893 had been appointed assistant physician.

In 1894 Ford Robertson—for a year, in collaboration with Middlemass—commenced a series of papers planned systematically to elucidate the pathology of the nervous system in relation to mental diseases. The joint papers, on the morbid changes met with among the insane in the scalp, skull, and membranes, and on the weight and other characters of the brain, as well as those by Ford Robertson himself on the changes in the vessels of the brain, first appeared serially in the *Edinburgh Medical Journal* from 1894 to 1896. He continued to carry out the original scheme single-handed by a series of brilliant researches on the changes in the neuroglia, nerve cells, and nerve fibres of the brain, the results of which were published later in various medical and scientific journals. Ford Robertson's splendid work had now attracted much attention both at home and abroad, and those who realized its value felt that it would be a lasting gain if the services of such a gifted and enthusiastic researcher could be permanently retained. In this way arose the "Scottish Asylums' Pathological Scheme" with its Conjoint Laboratory, and by the unanimous consent of its supporters Dr. Ford Robertson was appointed its first pathologist in 1897. The scheme owed its initiation to the foresight of the late Sir Thomas Clouston, its development to the co-operation of the majority of the other medical superintendents of the Scottish Asylums, and its final establishment to the backing and financial support of the contributing Asylums Boards, supplemented in later years by occasional grants from the Carnegie Trust, or from the Treasury or Medical Research Council through the General Board of Control for Scotland.

Ford Robertson's record as pathologist to the Scottish Asylums from 1897 till his death was one of incessant and exacting labour. The routine work of the Conjoint

Evidence of the occasional presence of strong contraction of large arteries (brachial, etc.) in diseased conditions in Professor G. Spencer Mclintock and Dr. J. L. Ross, in an investigation of blood pressure a number of years ago, and surviving sclerosed arteries from the legs of old horses were found to show extraordinarily intense contraction, causing complete obliteration of their lumen and enormous resistance to attempts to force blood through them. In relation to the question of arterial spasm, doubt as to the existence, at least in effective degree, of vasomotor innervation of the coronary arteries is not a consideration of decisive moment. For there is no proof that the forms of excessive contraction now under discussion—for example, in the brachial artery or the horse's leg, etc.—are vaso-motor phenomena; it is more probable that they are directly dependent on morbid conditions present in the arterial muscle at the time. It may be argued that the foregoing considerations point to the feasibility of the hypothesis of coronary spasm, in view of there being no sufficient reason to assume that the coronary vessels—especially prone as they are to sclerotic changes—should in diseased states be immune from such functional disturbances as seem to occur in other arteries. But the question is far from being closed.

**Fatal and Non-Fatal Angina.**

It is necessary to discriminate clearly between the separate questions of (1) the mechanism of pain production in anginal attacks, and (2) the mechanism of death occurring during or between attacks, sometimes without warning. The striking tendency of the greater forms of angina to terminate in sudden death need not be emphasized. There is every reason to believe that, in many cases at least, the end comes by ventricular fibrillation, and that the difference issue in fatal and non-fatal cases hangs on the superintending of fibrillation in the former and its absence in the latter. The development of fibrillation as a frequent and characteristic result of defective coronary blood supply, as demonstrated experimentally, has already been described; and we know, from abundant pathological evidence in man, the association of coronary and myocardial impairment with fatal angina. Further, the clinical features of many recorded anginal cases, where sudden death took place either in an attack of pain or apart from such, are very noteworthy in their similarity to those attendant on death by ventricular fibrillation. The significance of these facts taken together need not be enlarged upon.

If we accept the view, which has commanded itself to many observers, that an important factor in the production of pain in angina is to be found in the heart muscle working with a defective blood supply, it becomes plain how increased demands on the organ by muscular effort or emotional stress may excite an attack by leading to a relative anaemia, the blood supply, which was sufficient during rest to ensure the absence of pain, now becoming inadequate for the muscle. Such a conception might be brought into relation with the results obtained in an ischaemic limb where, on working a muscle, acute pain is caused long before the fatigue point (as indicated by inability to raise the weight in ergograph experiments) is reached—a mechanism of pain production apparently different from that present in a muscle working to fatigue while its normal circulation is going on (MacWilliam and Webster).

It may be conceived that in the close and striking association of angina and sudden death we see the working of distinct but related mechanisms, based in part at least on a common underlying process, essentially similar in character but differing in intensity and in the fatal or non-fatal issues, these issues being no doubt also influenced by other conditions which affect the results of the fundamental process. A conception of this kind would include more or less transient attacks of varying grades of severity, the other with the process, common to the two categories, going further in some directions, attaining greater intensity, and culminating in ventricular fibrillation.

tion. But the pros and cons of the vexed question of pain production in angina are beyond the scope of this paper. In connection with the well known fact that pronounced coronary sclerosis very frequently exists without angina, it has to be borne in mind that an essential point is, not the structural change in the arterial wall, but the amount of actual defect of blood supply through the sclerosed vessels from greater or less narrowing of their channels, the presence or absence of contraction in their muscular coats, on the more or less gradual development of obstructive change, the establishment of more or less efficient collateral circulation, etc. It is known that life may go on after the gradual development of complete occlusion of one coronary artery; also after complete blocking of a large branch. Collateral circulation obviously plays an important part; it is now well known that the coronary branches are not end arteries, as was at one time believed, but have numerous anastomotic connections. Further, as described by Gross, the blood vessels (arterial and venous) of the subpericardial fat, which increases in amount as life advances, can in some measure exercise a compensating influence, supplying a considerable amount of blood to the subjacent muscle. Belonging to this system are delicate parallel vessels accompanying the coronary branches, as well as a few of the fat of the antero-lateral groove. Gross emphasizes the importance of a ventricular anastomosis of the muscular walls of the right heart in old age, as bearing on failure in pneumonia, etc.; he suggests a variation of the age that a man is, as old as his arteries "to as old as his right coronary artery." It is noteworthy that when the main trunks and large branches of the coronary arteries are the seat of pronounced sclerotic changes the intramural twigs and finer ramifications may remain practically unaffected. The extent and efficiency of the capillary system are obviously of prime importance.

**Angina from Ventricular Stenosis due to Heart-block.**

In cases of heart-block, Adams-Stokes syndrome, etc., where death occurs suddenly, it is uncertain whether simple stoppage of the ventricular beat in the state of diastolic relaxation always lasts long enough to kill by paralysis of the nerve centres, following the phases of unconsciousness and convulsive phenomena. The time needed in man for irretrievable damage of these centres by ante anaemia is not known; in the ordinary experimental animals it is relatively long—a number of minutes. Of course, there may sometimes be morbid conditions present in man which would shorten the time that circulatory arrest can be survived. But in view of the associated structural damage present in the Adams-Stokes syndrome, the possibility of the ventricular standstill terminating in fibrillation in some instances must not be overlooked, though there seems to be no present or actual evidence of this happening in man. On the other hand, it is true that a fall of blood pressure, such as accompanies ventricular standstill, exercises a restraining influence on the development of fibrillation under certain conditions, but this does not always hold good under other conditions—for example, fibrillation sometimes develops in the gravely depressed or dying heart, notwithstanding the fact of excessively low blood pressure. In any case it must be concluded that only a fraction of cases of sudden death can possibly be attributed to ventricular standstill depending on the relatively rare condition of heart-block.

**Syncope during Tachycardia.**

There is strong reason to believe that the fibrillation mechanism is operative in many cases of sudden death associated with ventricular tachycardia. The myocardial conditions underlying tachycardia are closely related to those on which fibrillation is dependent, and there is abundant evidence that the former may develop into the latter. The excessive rate of beat—whatever be the origin of the tachycardia—is in itself favourable to this development, since it involves shortening of the refractory period and lengthening of the conduction time. The rapidity of succession of contractions—whether arising in the ventricles

**ANDREW STEWART, L.R.C.P. AND S. EDIN.,**

Consulting Surgeon, Birkenhead Borough Hospital.

Dr. Andrew Stewart died on July 30th, aged 69. He was educated at Liverpool and St. Bartholomew's Hospital, and took the diplomas of L.R.C.P. and S. and L.M. Edin. in 1881. After serving for fifteen years as honorary acting surgeon to the Birkenhead Borough Hospital he was appointed consulting surgeon to that institution.

Sir James Barr (Liverpool) writes: By the death of Dr. Andrew Stewart, Birkenhead has lost a very notable medical man and one who will be long remembered by all who knew him. For the last ten years or more he suffered from the incapacitating effects of chronic myocarditis, but he did not allow his disability to interfere with his work or pleasure. Although he long recognized that his terminus would be abrupt, and he spoke freely of it with the greatest amount of sang-froid, he was ever one of the cheeriest of mortals, and it did not require to be long in his company to feel that whatever might be the condition of his heart his alert mind would serve him to the last. His end came very suddenly in the presence of his devoted wife, while sitting at his desk writing a letter. For Andrew Stewart death had no terrors, and he died as he lived, beloved and respected by all who knew him. He took great interest in his professional work, was a diligent reader of the medical journals, a man of wide general culture, and fond of sport—devoted to boating and golf. In many respects he would have made a fair Sherlock Holmes. He leaves a widow, son, and daughter to mourn their loss. His son is in the army, and at present serving his country on the frontier of India. His brother, Mr. Gershom Stewart, is a well known Member of Parliament, and one ever ready to throw his weight into the service of the medical profession.

**FREDERIC J. KNOWLES, M.R.C.S., L.R.C.P.,**

Honorary Secretary, St. Helens Division.

By the death on July 27th of Dr. Frederic Joseph Knowles the profession and the citizens of St. Helens and district have suffered a grievous loss. Dr. Knowles was born in St. Helens and received his medical education in the University College of Liverpool and London. After obtaining the M.R.C.S. Eng. and the L.R.C.P. Lond. in 1885, he commenced practice in his native town. He had been honorary secretary to the St. Helens Division of the British Medical Association since 1913.

Dr. Knowles was a keen volunteer and retired in 1910 as lieutenant-colonel. He was honorary colonel R.A.M.C., and had received the Territorial Decoration. For thirty years he had been an examiner to the St. John Ambulance. He took an active interest in athletics—swimming, tennis, and cricket—and was a freemason.

His funeral, which was of a military character, was attended by almost every doctor in the district, and the streets of the town were lined by sympathetic crowds. The death of Dr. Knowles has removed an outstanding figure from the professional and social life of St. Helens.

Dr. ALEXANDER MACKAY of Crook, co. Durham, who died on June 23rd, aged 78, was educated at the Universities of Edinburgh and Glasgow; he graduated M.B., C.M. at the latter in 1870, and M.D. in 1874. After serving as assistant surgeon to the Glasgow Ophthalmic Institute and to the Glasgow Royal Infirmary, he took over, at the age of 22, the practice of the late Dr. Kelby of Crook, which grew to very large dimensions. Dr. Mackay was medical officer of the Crook District of the Auckland Union and physician to Ushaw College. He was a great sportsman and hunted regularly, until two years ago, with the South Durham and the Marquess of Zetland's hounds; he was also a keen farmer, and until recently owned and managed a farm. He was an old member of the Bishop Auckland Division of the British Medical Association and a justice of the peace for the county of Durham. He is survived by two sons and a daughter, one of his sons having succeeded him in his practice.

Dr. LOT ALBERT TAYLOR, who died suddenly at Kidderminster on July 20th, practised until a short time ago at Kinver, Stourbridge. He was educated at Queen's and Mason Colleges, Birmingham, and took the diplomas of M.R.C.S. Eng. in 1886 and L.R.C.P. Edin. in 1887; he took the D.P.H. in 1889. After holding house appointments at the General Hospital and Queen's Hospital, Birmingham, he went into practice at Kinver, where he was medical officer and public vaccinator for Kinver District of Seisdon Union. Dr. Taylor was indefatigable in the work which he did for the Dudley Division of the British Medical Association, of which he was honorary secretary and formerly chairman; he did valuable work also on the Panel Committee. During the war he had charge of fifty beds at the Wordsley Military Hospital, and he undoubtedly suffered from the strain of this in conjunction with his practice. He was a justice of the peace for the county of Stafford, and everywhere earned respect and affection.

Dr. ALEXANDER BRODIE SETON STEWART, O.B.E., who died suddenly at Watford on July 3rd, was educated at the Leeds Medical School; he took the L.S.A. in 1894, and became L.M.S.S.A. in 1907. He was given a commission in the R.A.M.C. (T.F.) as lieutenant in the 1st West Riding (Leeds) Field Ambulance, becoming captain in 1910, major in October, 1914, and lieutenant-colonel in June, 1916. For his services in the war he received the O.B.E. in 1919, and also the third class of the Serbian Order of St. Sava; the Territorial Decoration was conferred upon him in 1920.

**Universities and Colleges.****UNIVERSITY OF LONDON.**

A MEETING of the Senate was held on July 18th.

The following were recognized as teachers of the University in the subjects and at the institutions indicated:

*St. Thomas's Hospital Medical School.*—Dr. S. E. Dore (Dermatology), Colonel L. W. Harrison (Venereal Diseases), Dr. R. C. Jewsbury (Pædiatrics).

*University College Hospital Medical School.*—Mr. H. D. Wright (Bacteriology).

*St. Mary's Hospital Medical School.*—Mr. G. W. Ellis (Chemistry).

The title of Emeritus Professor was conferred on Dr. W. D. Halliburton, F.R.S., on his retirement from the chair of physiology at King's College, which he had held since 1890. The title of Assistant Professor of Anatomy at University College was conferred on Dr. Herbert H. Woollard.

Regulations for the academic diploma in psychology were approved and will be obtainable from the Academic Registrar in September.

It was resolved that the regulations for the M.D. examination for internal students be amended by the addition of the following before the first complete paragraph on page 276 of the Red Book, 1922-23:

Any exemption granted to a candidate under the foregoing paragraph will hold good only at the M.D. examination immediately following the acceptance of his thesis. At any subsequent entry for the M.D. examination he must either take the whole examination or submit the same or another thesis for consideration in connexion with such subsequent entry.

The regulations for the M.S. examination for internal students (Red Book, 1922-23, p. 282) were directed to be similarly amended and corresponding amendments were made to the regulations for external students.

Mr. C. C. Choyce, C.M.G., was appointed an examiner in surgery for the year 1923-24.

Mr. H. J. Waring was appointed a governor of East London College, and Mr. Raymond Johnson was nominated as a member of the Westminster Hospital Medical School Committee.

The following have been elected chairmen for 1923-24 of the committees indicated: *Council for External Students*, Dr. E. Graham Little; *Co-ordination and Developments Committee*, the Vice-Chancellor (Mr. H. J. Waring).

The Semon lecture for 1922-23 on the Advancement of Laryngology will be delivered by Dr. A. Logan Turner in the rooms of the Royal Society of Medicine, on Thursday, November 1st, at 5 p.m.

**LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE  
FOR WOMEN.**

The following scholarships have been awarded for session 1923-24:

*Fishmongers Exhibition for Girls*: Winifred Harris. *Poststock Scholarship*: Alice Hodge. *St. Dunstan's Medical Exhibition*: Joyce Woods. *Mrs. George M. Smith Scholarship*: Kathleen Gambrell. *Dr. Margaret Todd Scholarship*: Dorothy Wilkins. *B. & C. Mabel Sharrman Crawford Scholarship*: Marquerite Penn. *Sarah Holborn Scholarship*: Ivy Varley. *Isabel Thorne Scholarship*: Jocelyn Tracey. *Dr. Edith Poohy Phipson Post-graduate Scholarship*: Gladys Webster, M.B., B.S.

good blood pressure—vastly higher than what is necessary for the continuance of life. Pronounced slowing (without danger to life as a rule) is, of course, familiar in some forms of violent pain—for example, in biliary and renal colic, etc. The conditions under which sudden death most commonly occurs—namely, muscular exertion—are not favourable to prolonged vagus inhibition, but on the contrary are associated with reduction of the normal vagus control over the heart and concomitant activity of the augmentor nerves, leading to acceleration with increased force of the beats, etc.—conditions favouring the development of fibrillation in predisposed subjects. The same holds good generally in emotional excitement, apart from the very brief standstill (or prolongation of diastole) which may be caused by sudden fright.

#### Vagus Inhibition succeeded by Fibrillation.

There is another possibility with reference to the effects of vagal inhibition. Experiment has shown that attacks of auricular fibrillation of varying duration sometimes develop after a period of inhibition, sometimes after one or more recommencing auricular beats have occurred. The development of fibrillation in these instances is definitely related to the occurrence of the preceding phase of inhibition induced by vagus stimulation.

Fibrillation of the ventricles has also been seen following vagus standstill, but this is a rare phenomenon as compared with the development of auricular fibrillation in similar circumstances. In the course of researches over a great many years I have obtained records of only a very few examples. Still these are enough to indicate that, in presence of undue ventricular susceptibility, fibrillation may sometimes be determined in this way in some of the manifold varieties of abnormal conditions that can occur in man. Thus vagus inhibition, much too brief to be dangerous through the standstill induced, may possibly involve a mortal issue through a succeeding fibrillation.

#### Fibrillation or Reflex Inhibition in Sudden Death in Anginal Subjects.

The following considerations may be cited in favour of the fibrillation view of death in angina.

1. The presence of coronary and myocardial conditions which are known in certain circumstances to predispose to fibrillation. The inevitable or almost inevitable occurrence of coronary lesions in cases of fatal angina is a matter of general agreement. Sir Clifford Allbutt has adduced a wealth of facts and considerations marshalled with his usual skill, in favour of his view of the aortic origin—as contrasted with coronary and myocardial origin—of anginal pain. But this veteran clinician at the same time recognizes that the question of a fatal issue to an anginal attack is essentially associated with the condition of the myocardium.

2. The recognition by numerous observers, in some anginal attacks, of acceleration of the heart's action with irregularities, extrasystoles, etc.; such are known in many conditions to herald the onset of fibrillation. Among others, Windle recorded a fatal attack of angina in which the heart rate rose from 75 to 150 and became very irregular.

3. Though some slight slowing of the heart may occur in an anginal attack, there seems to be no direct evidence of the occurrence of pronounced inhibition, such as might, if somewhat intensified, threaten a suddenly fatal issue; the degrees of inhibitory slowing observed have been far removed from determining circulatory failure or even causing any considerable fall of blood pressure. There seems to be no relation between the severity and duration of the pain and the tendency to die in the pericardium.

4. Death often occurring at the beginning of an anginal attack or in one that is relatively slight as regards pain, etc., is probably of the same mechanism as absolutely sudden death, with occurring between attacks or during relaxation of angina; the considerations bearing on such subjects are probably applicable to deaths during anginal attacks.
5. In the case of death between attacks or during relaxation of angina, there is no evidence of such powerful different excitation as might be supposed to produce cardiac inhibition of such intensity and duration as to be fatal.

Rupture of the heart is a very rare accident. Simple standstill of the ventricles in complete heart-block can only be a rare cause—assuming that such standstill may sometimes kill without fibrillation as the terminal event. As has been stated, it is open to grave doubt whether reflex vagal inhibition *per se*—that is, without the superposition of fibrillation—is responsible for many deaths. Blocking of the mitral orifice by a thrombus and embolism of the pulmonary artery are known to be of very rare occurrence. (Thrombosis and embolism of the coronary arteries kill, as has been already stated, by fibrillation.) The old idea of a heart that is working with fair efficiency abruptly "failing to contract" against excessive resistance may be set aside as untenable, in the absence of the sudden action of violent poisons, etc.

There remains the conclusion that the great majority of absolutely sudden deaths are to be ascribed to ventricular fibrillation.

#### Symptoms of Ventricular Fibrillation in Man and Animal.

The similarity between the group of symptoms associated with many cases of sudden death in man and those attendant on ventricular fibrillation experimentally induced in animals is indeed striking. The abrupt abolition of pulse, cardiac impulse, and heart sounds, the sudden fall of blood pressure, unconsciousness, muscular relaxation often preceded by a brief phase of rigidity or convulsive movement, dilatation of the pupils, and the continuance of slow deep respiratory movements, are identical in animals and in the human subject, while in the latter the speedy replacement of the subject, intense pallor by lividity or marked cyanosis is a notable feature. The amount of colour in the face, together with the occurrence of several respirations after the collapse, have sometimes made onlookers somewhat incredulous that death has taken place. The occurrence in some cases of premonitory features such as extra-systolic irregularities, bouts of tachycardia, etc., is significant. It is important that, in the collection of evidence as to unexpected and unexplained death, special attention should be devoted to ascertaining the occurrence of the group of associated features just stated: these have been very definitely recognized in many cases of sudden death where accurate observations have been made. Some such cases have come under the direct observation of the writer.

No doubt some of these phenomena are common to certain other forms of sudden circulatory failure—for example, from heart-block, collapse induced by violent afferent impulses (blow on epigastrium, etc.), or in certain cases of auricular flutter, etc. But there are special features in some of these—for instance, as regards the behaviour of the respiratory centre, etc.

#### Protective and Remedial Agencies.

In animal experimentation—on cats, which are remarkably liable to ventricular fibrillation—the use of certain drugs has been found by the present writer<sup>1</sup> (working in conjunction with Professor Spencer Mletín and Dr. J. R. Murray) to have decidedly beneficial effects, both in the way of protection against the onset of persistent fibrillation (for example, against fatal cardiac currents one hundred times as strong as are usually effective) and—in combination with cardiac massage—as regards recovery from the actual attack. These methods are at present only applicable under experimental conditions. But they give some ground for hope that, with fuller knowledge of the conditions that induce the inception and persistence of fibrillation, much may be possible in the future as regards the warding off of such catastrophic happenings as often bring life to an unexpected end.

## Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

THE postal address of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitology*, *Westrand*, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, *Westrand*, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, *Westrand*, London; telephone, 2630, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### VACCINATION.

DR. D. W. SAMWAYS (Clyst St. George, Devon) writes: Now that vaccination is being so generally performed it seems to me desirable that definite instructions regarding treatment are necessary. Should the arm be first cleaned with an antiseptic, or with, say, boiled water? Should boric lint, which appears so commonly employed, be fixed over the part afterwards, or replaced by a shield? If the boric lint be meant as an antiseptic to restrain the pustule, its employment appears unscientific if the pustule be intended to develop. In any case, the lint generally works and breaks the pustule, to which it afterwards adheres, and presumably disinfects. If the vaccination be completed by the entry of the vaccine into the system, say, in half an hour, and the local reaction be neither necessary nor desirable, even more active disinfection might be profitable; but if the pustulation be essential, a disinfecting pad seems out of place and a protecting shield appears indicated. I think my ignorance on the subject is shared by many, who would appreciate enlightenment in your columns.

#### MASTICATION.

"FLETCHERISM" writes: Many of your readers must have been interested in the recent letter from Mr. Morley Roberts (June 23rd, p. 1077) regarding mastication. Can anyone inform me: (1) What recorded confirmations have there been of Fletcher's theory? I know *Diet and Endurance*, the book where Professor Irving Fisher recounts an experiment where a number of American students put in practice Fletcher's advice of a diet largely, though not wholly, vegetarian, coupled with very thorough mastication. The results in endurance are almost unbelievable, except that Dr. Irving Fisher is a man of standing and reliability. (2) Are Horace Fletcher and his British co-worker, Van Someren, alive or dead? If dead, did they live to a good old age, practising their special masticatory habits, and was their bodily vigour unusually maintained because of this?

#### INCOME TAX.

##### Car Transactions.

"B. K. N." replaced a 13.9-h.p. V car, which he had bought second-hand for £210, by a new 13.9 F car costing £667, the then cost of a new 13.9-h.p. V car being £450. The old V car was sold for £102, so that "B. K. N.'s" total net expenditure was £667 - £102 = £565, and he claims to deduct £450 - £102 = £348 as the cost of replacement.

\* \* \* There were two elements of improvement in the transaction; the new car was of a superior standard, and it was new as compared with the one which "B. K. N." bought second-hand; and both elements have to be eliminated in ascertaining the replacement cost, but he has eliminated the former only. The calculation requires knowledge of the cost of a new 13.9-h.p. V car at the time when the old one was bought. Suppose it to have been £x, then the cost of a similar second-hand car at the time when the F car was purchased would have been £210 ×  $\frac{450}{x}$  and the amount allowable as replacement is that sum less the £102 received.

### LETTERS, NOTES, ETC.

#### FREEDOM OF NEGRO RACES FROM CANCER.

DR. J. BELL WALKER (Ayr) reports that he saw a case of epithelioma of the penis in a negro in Nyasaland in 1924. This, it was said at the time, was the first known case of cancer in a native in those regions. The patient was sent by the medical officer at Chiromo and transferred to Dr. Walker's care at the Livingstone Memorial Hospital, Zanzibar, for operation. Chiromo, Dr. Walker continues, in those days when the railway was only being planned, was the station on the river Shire for passengers from and to the various European centres in Nyasa-

land, and the patient, no doubt, would come a good deal into contact with European civilization. The contention (Dr. Bell Walker adds) that no "unsophisticated" negro contracts this disease would seem to be at least not negated by this case.

DR. AGNES SAYILL (London) suggests that the immunity of negroes points to the existence of some factor in common for all simple living races. She asks for facts as to the main diet of these races.

#### TUBERCULOSIS, NOTIFICATION, AND HOUSING.

"M.R.C.S., L.R.C.P." writes: Being a general practitioner I read with due respect the statement of some "tuberculosis specialist" that there is much less tuberculosis than there was some years ago. The proof given was that far fewer cases were notified. This sort of reasoning is fallacious. Chronic cases all over the country have been notified and live on to a ripe old age and only the new developments are notified and so the public are told that there is less tuberculosis. The absurd expense of keeping up an army of tuberculosis officers is obvious to the general medical practitioner who sees the amount of actual treatment meted out by them. The tuberculosis officer keeps records and makes statistics and now and again a case is sent to a sanatorium, but for one case sent there are ninety-and-nine who get no treatment, but then they have the pleasure of being notified and their illness made public property—if anything is done. Personally I have notified one case in the last twelve months: the patient has never seen nor heard of the tuberculosis officer nor the medical officer of health. My firm opinion is that the money spent on tuberculosis officers and the tuberculosis scheme should go direct to the building of houses. More houses and less statistics seems to me to be the common-sense method of treatment.

#### "POISONOUS PLANTS OF ALL COUNTRIES."

DR. A. BERNHARD-SMITH (London) writes: Your reviewer (July 21st, p. 110) is good enough to suggest a botanical classification of the plants I describe in this work rather than that which I have adopted. I stated, however, in the preface to the first edition, that my classification was based on that given by Drs. Guy and Ferrier in their textbook on medical jurisprudence, and see no reason to alter it now. If in error, I flatter myself that I am in good company. With regard to the poetical quotations, I am afraid that the one selected for adverse criticism is somewhat unfortunate. Swinburne, in the poem, "The Garden of Proserpine," puts a comma after his line mentioning poppies; and I shall maintain that the stanzas following, which I quote—

"Green grapes of Proserpine  
Where no leaf blooms or blushes  
Save this wherewith she crushes  
For dead men deadly wine"—

are an approximately adequate illustration for *Tamus communis*.

#### TOPOONYMY SIMPLIFIED.

THE "Ignorant Student" to whose theory of a white or wight element in many place names reference was made recently has been so obliging as to send us another pamphlet bearing the same general title *Origins in Place Names*, but with the subtitle *Sounds*. Here he would carry us very far—out of all whooping—to the origin of languages. He would have us believe, or so we understand him, that all place names mean the same. Gutturals, he argues, would come first, when man began to try to communicate with man by sound, and the first word would be gha. "It has been computed," the Student says, "that there are no less than thirty-seven different values of the g-sound in English alone;" starting with this liberal allowance he finds little difficulty in reducing "all place names to a single common unit of sound for their origin and to a single common meaning, such as light, white, shining." We may account thus for the bys through which Tennyson's brook ran, but how about the thorpas? It is a long way from that to gaga or even ghaga. There is, however, this to be said for the Student's theory, that to-day the infant's first attempt at speech is something like gha-gha, and the mother's first lesson is to transform it into a polite expression of thanks.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 34, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 104.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                             | £   | s.  | d.     |
|---------------------------------------------|-----|-----|--------|
| Six lines and under                         | ... | ... | 0 9 0  |
| Each additional line                        | ... | ... | 0 1 0  |
| Whole single column (three columns to page) | ... | ... | 7 10 0 |
| Half single column                          | ... | ... | 3 15 0 |
| Half page                                   | ... | ... | 10 0 0 |
| Whole page                                  | ... | ... | 20 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded. Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive posts *reclante* letters addressed either in initials or numbers.

**'PHILKUT'***The Stopping that stops there*

(Regd.)

The latest and best method of repairing cuts in outer covers. Why pay £3 for a new Tread when a tube of PHILKUT makes a good repair? So Simple—so Effective!

maintaining this material is scattered through numerous periodicals. It has been the object of the author to collect its scattered material into a single volume and present it in a concise form. The article on the stomach may be taken to illustrate the author's method of handling this material. After a fairly complete account of the normal physiology, the pathological changes in gastric motility are considered, special attention being given to vomiting, and on the basis of the considerations adduced, the question of vomiting during and after anaesthesia is discussed and the proposed remedies examined. Gastric pain is next dealt with—its origin generally, its relation to gastric ulcer and gastric contractions, and its diagnostic significance. In this connection gastric crises and the effects of nerve section are considered. Dilatation of the stomach from pylorospasm and atony are then dealt with and the pathology of acute dilatation discussed at length. Under the heading of normal repair the histology of the healing of wounds of the gastric mucous membrane is described and its bearing on choice of sutures. Much space is devoted to gastro-enterostomy and the modifications of the gastric functions resulting from it, together with the complications that are liable to follow, such as gastric ileus and jejunal ulcer. The effects of pyloric transection, and total resection are considered in familiar detail. The chapter closes with a long discussion of the etiology of gastric, duodenal, and jejunal ulcers and the manner in which gastro-enterostomy promotes their healing. Other chapters treat of the mouth, salivary glands, tongue and oesophagus, abdominal organs, peritonum, pelvis, organs and male genitalia, thyroid gland, chest cavity, brain and spinal cord, and the extremities. Each chapter is followed by a copious bibliography, that on the stomach consisting of two hundred and sixty references. These are almost exclusively from German sources.

# ANNALS OF MEDICAL HISTORY.

The first number of the fifth volume of the *Annals of Medical History* has been delayed some three months. Edward Jenner's portrait appears on the cover, and the correspondence shows another and less pleasing representation of the discoverer of vaccination, whose life is briefly sketched in an editorial article. Otherwise this instalment has become accustomed to look for in this valuable periodical. Dr. Horace Manchester Brown's scholarly Mayo Foundation Lecture for 1921 on the anatomical habits of the soul traces opinions on this subject from Hammurabi to Terroir, who was probably the last medical writer to give the soul a local habitation in the body—namely, in the meninges. In 1596 Descartes, who at one time believed that the soul occupied the pineal gland, subsequently considered that it pervaded the whole body, and rejected all materialistic ideas of the soul. Dr. H. Vics contributes a note on the eponymic history of the ganglion seminale (Gasser), showing that it was first described in 1765 by A. B. H. Hirsch, a pupil of Lorenz Gasser of Vienna. The dead but significant controversy between Rioloan and Harvey is briefly described by Dr. John Donley. A very interesting account of William Edmunds Horner (1793-1853), Professor of Anatomy in the University of Pennsylvania for twenty-two years and the describer of the tensor tarsi muscle and the cartilages at the bronchial subdivisions, is given by Dr. W. S. Middleton. Since 1919, when the 286 incunabula in the library of the College of Physicians of Philadelphia were catalogued in the *Incunabula*, such notable additions have been made that Mr. C. P. Fisher now publishes the descriptions of the whole, which now totals 332. Dr. J. E. Sands, in a review of an early paper on malaria, shows that twelve years before Laveran's discovery Meigs, Rhoad, and William Pepper recorded a malarial parasite in the first volume of the *Pennsylvania Hospital Reports*.

*Annals of Medical History* (Spring Number, 1923). Vol. V, No. 1. Edited by Francis R. Packard, M.D., New York; Paul H. Hoeber; London: Baillière, Tindall and Cox, 1923. (Pp. 94; illustrated. Subscription in Great Britain £2 2s.)

In a recent pamphlet Dr. P. MATHIAS, bacteriologist of the Tropical Institute at Hamburg, gives an account of the conditions he met with in Russia when as director of the German Red Cross Expedition he visited that country in September, 1921. There appears to be little doubt that the extent of the famine and epidemic disease which devastated Russia in the years 1921 and 1922 was unparalleled in the modern history of Europe, although periods of starvation followed by pestilence have been frequent in Russia since the earliest times. As the result of the failure of the harvest in 1921 it was estimated that by April, 1922, the number of starving persons in Russia, including the Ukraine, was 40 millions. The mortality was highest among children; the death rate in the first year of life was put at 80 to 100 per cent, and in older children at 30 to 40 per cent. Substitutes for bread were made from bark, acorns, grass, straw, and even clay. Numerous cases of coprophagia were reported, particularly among children. Well authenticated instances of necrophagia and cannibalism occurred, as in previous periods of the history of Russia, especially in the famine years of 1230-51 and 1601-2. The diseases following in the train of famine were hunger, oedema, scurvy, nomia, intestinal diseases, dysentery, enteric, and, most important of all, typhus and relapsing fever. The last two diseases were spread in the crowded railway carriages and waiting rooms, and homes and camps for refugees, whose loneliness beggared all description, as well as in common lodging houses in the large towns, and also in the hospitals. Whole families fell during the railway journey and many died in the carriages or on their arrival. Owing to the disorganization of the sanitary service the number of notifications did not represent the actual number of cases, but in the Ukraine alone it was estimated that during the first four months of 1922 there were 137,083 cases of typhus, 53,578 of relapsing fever, and 42,388 of enteric. In 1921 alone there were 176,886 cases of cholera in Russia, as compared with not more than 50,000 cases during the whole course of the war. No reliable statistics were available concerning malaria. Owing to the exhaustion of the population by famine and disease the carrying out of effective sanitary measures was practically impossible; but Dr. Mathias pays a high tribute to the Russian medical practitioners and men of science, who, with the most primitive equipment and in unheated laboratories and often without gas or electricity, were able to carry on work of the highest order.

## A TEXTBOOK OF OTOTOLOGY.

Sir WILLIAM MATHIAS and Dr. WILFRED WINKEL have produced a *Practical Handbook of Diseases of the Ear*, which has some resemblance in style and appearance to their much larger work on diseases of the ear. The new volume, whilst covering the essentials of the subject, is less than half the size of the other, and should prove useful to senior students. The authors write with the experience gained from both the clinical and pathological aspects, so that the features which have made the larger volume so valuable as a book of reference and a permanent contribution to medical literature are again to be discovered here. The most important part, which refers to examination of the ear and nose, is well and succinctly done, and if the student will read this section with care and put the directions into practice he will soon acquire a good and systematic method of examining patients. The most serious criticism which must be offered is the lack of balance in apportioning space to the various subjects. Thus, although the book only contains 191 pages including the index, the reader must turn page 108 before penetrating as far as the outer surface of the membrana tympani. The space given to diseases of the middle ear, internal ear, and intracranial complications seems therefore unduly limited, whilst many rare conditions of the auricle

*Die Russische Hunger- und Seuchenepidemie in der Jahren 1921-22.* Von Professor Dr. P. Mathias, Sonderbdruck aus *Zeitschrift für Hygiene*, Band 99, Berlin: J. Springer, 1923. (Lied. 60p. pp. 23; 24 figures, 25. 6d.)  
*A Practical Handbook of Diseases of the Ear for Students.* By William Mathias, M.D., and Wilfrid Winkel, M.D. London: W. B. Saunders, 1923. (Demy 8vo. pp. 191; 72 figures, 12s. 6d. net.)

and the rest of the curve would draw a horizontal line as the stomach empties. It means that the percentage of HCl is decreasing owing to neutralization by an alkali, because as the acid curve descends the inorganic chloride curve rises and the two cross one another. (Fig. 1.) Sodium chloride has been formed by neutralization and increases in amount as the acid decreases; the sodium chloride curve thus represents the curve of neutralization, which in its turn depends upon relaxation of the pyloric sphincter. The fall in the HCl curve and the concomitant rise in the NaCl curve thus result from pyloric relaxation and duodenal regurgitation and are a measure of the degree of pyloric tonus. In those cases in which the acid curve does not fall the inorganic curve remains low during the whole period of digestion, showing that in these people pyloric tone is abnormally maintained. (Fig. 2.) It must not be supposed that duodenal regurgitation occurs at the same time and to the same extent in all individuals with the normal type of curve, because this is not the case, as the great variations in the curves demonstrate. We can, however, state, using Bennett and Ryle's figures, that in about 90 per cent. of normal individuals the amount of gastric juice secreted and the degree of duodenal regurgitation vary within certain limits, but that they all conform to a common type: in about 5 per cent. duodenal regurgitation is abnormally defective; and in a few people congenital achylia is present, which condition has been recognized for some years.

There are great difficulties in the way of the investigation of disorders of function of the stomach, because the deviation from the normal and the return to it must vary in accordance with the type to which the patient normally belongs and of which we are ignorant. We must also remember that we investigate our cases with a comparatively non-irritating standard fluid and that this is a very imperfect test of the manner in which the stomach reacts to ordinary food of different kinds. Neither is our method of collection of the gastric contents during digestion an ideal procedure.

#### *Acid Dyspepsia: Hyperacidity of the Gastric Juice: Hyperchlorhydria.*

The functional disorder of the stomach to which the above names have been given is a well defined and easily recognizable malady. It is the commonest form of irritability of the stomach. It was formerly thought that the percentage of HCl in the human gastric juice was about 0.2, and this statement may still be occasionally found in recent textbooks. It was, and is at the present time by many, considered that a percentage of 0.25 total HCl and above in the gastric contents indicates a pathological excess of HCl in the gastric juice, and that this excess is the primary and essential cause of hyperchlorhydria. The fact is, however, that the human gastric juice contains the same percentage of HCl as that of animals—namely, 0.4 to 0.5—and that the percentage of HCl in the gastric contents represents the percentage of this acid in a mixture of gastric juice and food. In a series of unpublished experiments by E. K. Martin and myself it was found that after feeding on Glaxo the percentage of HCl in the gastric contents of cats never rose above a maximum of 0.12, although the pure juice obtained from a Pavlov fistula at the same time was constantly in the region of 0.4. The only primary alteration in the gastric juice which affects the percentage of HCl in the stomach contents is that in the quantity secreted. In the condition of hypersecretion there may be an increase in the average percentage in the stomach contents, but this is not necessarily so. If the gastric contents leave the stomach more rapidly than usual the HCl percentage also tends to rise above the normal average, but neither of these two factors is the common cause of the functional disturbance under discussion, because there is hypersecretion only in a certain number of cases and the food does not usually leave the stomach more rapidly than normal. Neither is the high acidity maintained in these two conditions unless there is pyloric hypertension. The essential cause of hyperacidity of the gastric contents is a deficiency in the neutralizing process

which regulates the acidity of the contents and keeps the percentage of HCl at about 0.2. Duodenal regurgitation of the intestinal contents fails to occur during digestion in the normal fashion, with the result that the HCl curve continues to climb till the stomach is empty; or it may draw a more or less horizontal line, or it may show one or more dips owing to partial neutralization attempts. (Figs. 2, 3, 4.) The cause of this deficient regurgitation is irritability of the pyloric sphincter leading to deficient relaxation or spasm. The actual height of the HCl curve is not a matter of great significance. The important point to note is that the condition "hyperchlorhydria" is the result of neuro-muscular irritability of the stomach in which the pylorus plays the chief part.

#### *The Cause of Pyloric Hypertension.*

The irritability of the pylorus varies in normal individuals to some extent, so that there is a considerable latitude in the normal degree of pyloric tone, and hence the variations in the normal type of curve which are acknowledged to occur by all.

This irritability of the pylorus may be increased by one of two causes: (1) local disease in the vicinity—for example, ulcer; (2) irritability of the central nervous system, often produced reflexly. Even when either of these conditions is present it does not follow that the pylorus is unable to perform its functions normally, because it is one of the facts of medicine that in such diseases the disturbances of gastric function calling attention to them commonly appear only from time to time, and it is quite easy to relieve the patient although the diseased condition is still present. In 1920 Crohn and Reiss found that improvement in the symptoms of patients of this type depended upon the relief of pyloric spasm, and not upon alterations in the acidity of the contents or hypersecretion alone. Whether one is dealing with (a) a normal individual in the first instance, or (b) a person the subject of one of the two above pathological conditions, the exciting cause of the excessive pyloric hypertension is twofold; (1) food irritation, mechanical or chemical; (2) HCl. In proportion as the pylorus is irritable there is need of a smaller exciting cause: (1) The pylorus has a remarkable selective power. It is the regulator of the output of the stomach and holds up imperfectly disintegrated food and hard and irritating substances, whilst it lets pass finely divided and non-irritating materials and fluids. When such food is present in the stomach, the pylorus being particularly sensitive to it, the emptying of the stomach is delayed, and duodenal regurgitation necessary to neutralize the acid contents is prevented. Peristalsis increases and the intragastric pressure rises, regurgitation of the acid contents occurring into the lower end of the oesophagus or into the mouth. Our methods are unable to demonstrate all these changes, which vary from day to day according to the fatigue of the patient, the state of the nervous system, and the quality of the food eaten. (2) The part played by the HCl is not so simple. Normally the pylorus responds to the HCl in the stomach contents, relaxing in the presence of acid in the stomach and contracting when the duodenal contents are acid. In diseased conditions, however, it is perfectly well able to function normally either in the entire absence of HCl or in the condition of hypersecretion. The pylorus has therefore adapted itself to the new secretory conditions, but this only applies to a pylorus which is not in an irritable condition, for in this state of irritability its adaptability disappears and it reacts to free HCl as to other irritants. HCl in weak solution is a powerful irritant to living tissues. Nervous hypersecretion is thus likely to cause pyloric spasm and hyperacidity of the contents, and hyperacidity resulting from food irritation materially assists in keeping up the pyloric hypertension.

There are two methods of drug treatment of this condition of hyperchlorhydria which are interesting. (1) By the administration of alkalis one and a half to two hours after meals, which replaces the deficiency in duodenal regurgitation and relieves the symptoms. Crohn has shown that this is the correct time to give alkalis, because if taken at an earlier stage, when the acid curve is rising and secretion very active, alkalis simply cause a drop in the

the principal legal decisions affecting public health and local government, are amongst the new features included in this year's edition.

Stories founded on medical practice are common enough, but in *The Adventures of a Private Nurse*, by Miss E. A. Riddock, we have an example of a similar work written by a nurse. The book consists of fourteen chapters dealing with her life with various patients. Though the style is somewhat pedestrian, the stories are vivid and convey an air of sincerity.

The last edition of the *Financial Times Investors' Guide* was issued towards the close of 1912. Since that date the war and the subsequent unstable state of affairs have made it impossible to prepare a new edition which would tally in any way with its original purpose. The new edition (price 3s. 6d.) contains information that should be possessed by everyone who has dealings in money matters. It is given in a form that can be readily understood by those who have no technical knowledge. Separate chapters are devoted to the various classes of securities. The book appears to be a reliable guide for those who plan their investments on non-speculative lines. Present holders of the old railway stocks will find a useful table giving the names and amounts of stock in the new companies to be given in exchange for each £100 of stock of the old companies.

# MEDICAL AND SURGICAL APPLIANCES.

CORRESPONDENT OF DERMATITIS WIT.  
MR. A. WILSON ADAMS, M.S., F.R.C.S., ASSISTANT SURGEON,  
BRISTOL ROYAL INFIRMARY, BRISTOL.

The purpose of the splint is to secure dorsiflexion of the wrist. This is the position naturally assumed by the hand in grasping an object, and is recognized as the optimum position for ankylosis, since the grip is inefficient if the wrist is not dorsiflexed. When ankylosis is a possible sequel it is imperative during healing that the joint should be maintained in this optimum position. The splint consists of two side bars ventrally at palm and upper forearm, with dorsal strap over the wrist. The framework is made of duralumin wire 4 mm. in diameter. For an average man a continuous length of 26 in. is adapted to the sides of the forearm crossing the front of the palm. On the outer aspect the wire commences at the junction of the upper and middle thirds of the forearm and passes in contact with the latter straight to the wrist-joint. There it is bent outwards and dorsally to adapt it to the back of the first interosseous space till it reaches the cleft between thumb and forefinger, leaving the thumb free. This angle should be determined by placing the hand in the position which it normally assumes in making a fist. With the necessary slight obliquity the wire is next carried across in front of the heads of the metacarpal bones to the ulnar margin of the hand, along which it proceeds to the wrist, and following the inner aspect of the forearm finishes on a level with the outer wire. It should be noted that if the wire is not bent well away from the base of the first metacarpal. If the splint be used to regain extension in the flexed position and the wire is adapted to a partly ankylosed wrist the wire is bent up later as the deformity yields to the steady pressure of the dorsal strap. Joining the upper 2 inches of the wires and curving round in front of the forearm is a thin duralumin trough covered with leather. This holds the upper ends of the lateral wires rigidly apart and automatically maintains apposition with the arm owing to the tendency of the hand to flex and so tilt the trough dorsally. A strap and buckle pass over the back of the forearm at this level. To the ulnar wire at the wrist is attached a second strap with buckle. This passes over the back of the lowest inch of the forearm, round the radial wire, and then

The splint is shown with thumb ring in the above diagrams; in the upper from the radial aspect. Chamois pads from the ulnar and in the lower diagram and buckles are omitted from lower

1. It is comfortable to wear and inconspicuous. 2. It is lighter than other forms of cock-up splints and yet is of adequate strength. 3. It does not prevent the use of the digits for grasping and the wearer can dress himself, feed himself, write, shake hands, etc. 4. A minimum of worry from splinting is entailed. These are important factors when the patient is undergoing treatment lasting for months and where intermissiveness is great. 5. The need for removal of the splint is greatly reduced in cases where dressings have to be changed, as the surface of the part is almost entirely exposed.

Mr. H. MORTIMER WHARRY, F.R.C.S., LARYNGOLOGIST to the Mount Vernon Hospital for Diseases of the Chest, writes: In the antium trocar described below I believe I have been able to combine the simplicity and directness of the ordinary straight trocar and cannula with two points of safety without unnecessarily complicating the instrument. First, in puncturing the medial wall of the antium below the inferior turbinate further walls by means of a small ring placed round the cannula at a distance of 1/2 inch from its distal end, and 5/8 inch from the point of the trocar; this ring is very small and inconspicuous, in no way adding to any difficulty in manipulating the instrument. The inside the nose, but is quite sufficient to check the instrument. The second point is one of convenience, and consists in an improved joint between the nozzle of the syringe and the cannula. It sometimes happens with the ordinary joint that when extra pressure is required from the syringe, the nozzle flies out and the lumen is squirted everywhere. The improved joint can be held together by the finger and thumb with the utmost security. Provided that the syringe is punctured in the right place, and the Higginson's section of the Royal Society of Medicine. This instrument is not a set for sphenoidal puncture as the guard is too far back, but an instrument made by the same makers has a guard 5/8 inch from the point of the trocar, and is suitable for the sphenoid. I am indebted to Messrs. Meyer and Phelps for the excellent way they have carried out my design.

double back again to the buckle on the inner side; on the right-ness of this depends the degree of dorsiflexion of the wrist. Where greater security is desired at this point, as in Colles' fracture, the strap completely encircles the limb. Small chamois leather pads are attached to the straps where they press on the bones of the palm, wire is bent into a half-circle in which the thumb of the palmist wire is kept extended, so relaxing the extensor longus rests and is essential in all and essential in some cases that the splint be made to measure. For this Messrs. Ferris and Co., Bristol, require an outline of the hand and forearm traced on paper, palm downwards. The dorsal wrist strap is adjustable and presses the wrist forward, causing the required degree of dorsiflexion at the joint, the palm and forearm being fixed where they rest against the underlying frame ends.

**Indications for Use.**  
A. To support the wrist dorsiflexed during some healing process, as for instance—  
1. Sprains and injuries to bones about the wrist as in Colles' fracture, fractured carpal or metacarpal.  
2. During healing of wounds, either accidental or surgical, such as tendon transplantations or ganglionectomy.  
3. Inflammatory affections such as occupational tenosynovitis, painful rheumatoid affections, and tuberculous or septic infections.  
B. To correct the deformity of a dropped wrist—  
1. Paralytic dropped wrist—when a splint is needed for months or years.  
2. Partial fibrous ankylosis of the wrist in a dropped position following paralysis or inflammatory lesions.

## Special Advantages claimed for the Splint.

curve, which usually rises a trifle higher subsequently. Digestion is thus delayed. (2) By the administration of atropine, which relaxes the pylorus and brings down the acid curve by neutralization, in addition to diminishing the secretion.

#### Action of Atropine.

Since the introduction of the fractional meal many observations have been made with this drug and conflicting results obtained. Unfortunately most observers have taken a diminution in acidity of the gastric contents to indicate a diminished secretion, but, as we have seen, this view is erroneous. We have to consider two distinct points: (1) whether the acidity of the gastric contents is diminished by atropine, and (2) whether the amount of gastric juice secreted after the stomach is empty is also diminished. With regard to the first point, there is no doubt whatever that atropine is able to modify the acidity curve of the gastric contents. A complete chloride analysis will show that a rising curve may be converted into a single peak curve which falls in the normal manner. As the HCl curve falls the NaCl curve rises, showing that the fall in acidity is due to neutralization by pyloric relaxation and duodenal regurgitation. An abnormal acid curve has been converted into a normal curve by relaxation of the pyloric spasm by the atropine. (Fig. 5.) The total chloride curve is frequently lowered by about 10 or 20, showing that the secretion is also diminished. The correct method of estimating whether or not the gastric juice secreted in the fasting stomach is diminished by atropine is to continue the collection of the secretion after the stomach has

emptied. Crohn was the first observer who found that this secretion could be stopped by giving very large doses of atropine. We may conclude that atropine diminishes the gastric secretion more particularly in the fasting stomach, but the benefit it produces during digestion is perhaps rather due to its power of relaxing the pylorus and restoring the normal duodenal regurgitation. Uniform results are not obtained in all cases, neither does atropine invariably relieve the patient.

#### Pyloric Obstruction.

Very little need be said about pyloric obstruction except that it exhibits in a striking way the effects upon the various curves of the limitation of duodenal regurgitation, its effect being a purely mechanical one. When the stricture is marked the total chloride curve tends to reach its height fairly early, as in cases of hypersecretion, and also to maintain its high level. The acid curve remains parallel with it more or less. The NaCl curve is usually low from the first. Duodenal regurgitation occurs to a slight extent, but it is irregular and spasmodic. The curves indicate a steady output of secretion with small irregular neutralizations. The fasting stomach contains mixed pancreatic and gastric juices with food remnants, the amount of each depending on the degree of stenosis. All degrees of neutralization occur in slighter cases. (Fig. 8.)

#### Hour-glass Stomach.

A slight degree of hour-glass contraction shows a perfectly normal curve like that of an ulcer of the body of the

Fig. 16.—Duodenal ulcer; hypersecretion; no hyperacidity; excessive neutralization; rapid emptying.

themselves have no effect whatever either on the incidence of miners' "nystagmus" or on the age at which incapacity commences from miners' "nystagmus." This condition corresponds to that of earlier investigators, such as Snell, Druett, Stassen, and Coppes, and is in conflict with Anderson, who in 1920 contended that errors of refraction are the principal cause.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE EDUCATION.

The report presented to the annual meeting of the Fellowship of Medicine and Post-Graduate Association by the honorary secretaries, Mr. Herbert J. Paterson and Dr. Henry MacCormac, was as follows:

secretaries, 160 post-graduates have been enrolled. Of these 53 were resident in Great Britain, 61 from the Colonies, and the remainder from the United States, the Continent of Europe and special distant lands as China, Syria, South America, and Barbados. The Prince of Wales's Hospital, the Infants' Hospital, the Children's Clinic—Western General Dispensary, National Hospital, for Diseases of the Heart, the London Lock Hospital, In September last a very successful course in General Medicine was given by several of the post-graduate hospitals combined with Middlesex and St. George's Hospitals. Thirteen post-graduates were enrolled for the course. By the kind permission of the Royal Society of Medicine the series of weekly lectures has been continued at intervals. Many well-known physicians and surgeons have been good enough to deliver lectures, and the average attendance has been thirty.

Since January 1st, 65 new members of the Fellowship have been

150. "That the work of the Fellowship of Medicine continues to be controlled, and the number of regular annual subscribers is now 107 letters received from those who have availed themselves of the facilities provided."

The Fellowship of Medicine has been very successful in its efforts to carry them into effect, and as a result warmly welcomed and adopted by your Council, a special committee being appointed to carry them into effect, and as a result the various hospitals. These suggestions were the same committee for submission to the annual meeting according to the resolution passed by your Council. We are particularly glad to report that various refresher and special courses have been arranged right up to June of next year, so that throughout the whole year one or more courses will be available for those who desire to do post-graduate work. There is every hope that as a result of what is being done, London will become a live centre of post-graduate teaching.

Perhaps we may be allowed to quote from an article by Dr. Ernest F. Horne of

township, who spent some months in this country investigating the facilities for post-graduate teaching. "As to the future of post-graduate work in London I consider it very bright. I am certain from what I have seen that it is only a question of time when a wonderful institution will be opened."

"Once again we must express the great debt owed by the Fellowship to the Royal Society of Medicine for their continued support and generosity in placing an office at our disposal. The President of the Society, Sir William Hale-White, has taken a keen and personal interest in the new office which are being made and his valuable help has been given to us in many ways. In conclusion, we desire to place on record the appreciation of the honorary officers of the valuable and devoted service which the honorary, Miss Willis, and her assistant, Miss Roy, have rendered to the Fellowship of Medicine."

(Great regret was expressed by the members attending the meeting that Sir George Mackinnon had decided to retire from the office of President; a cordial vote of thanks to him was adopted. Sir Arbuthnot Lane was elected President in his place. The new constitution of the Post-Graduate Association of the Fellowship was unanimously approved. The constitution provided that the General Council should consist of twenty members, and they were accordingly elected. At a subsequent meeting the Executive Committee was also appointed, consisting of the honorary officers and seven members elected by the General Council.)

The report makes it clear that a distinction must be drawn between the presence of physical signs distinctive of miners' nystagmus and the existence of incapacity arising therefrom. Many observers in various countries have found that a large proportion of underground miners while still at work exhibit signs of miners' nystagmus, which, if complained of, might establish a claim for compensation. In America, where no compensation is given, little is heard of the existence of the disease. In Germany the incidence of claims was 0·3 per cent. to 1913, but on limiting compensation to the serious cases it has fallen to 0·03. In Belgium, with a uniform method of compensation the incidence has remained at 0·2 to 0·4 per cent. In England the admission of cases of dysphoria to compensation increases the incidence of claims; the rise and fall of wages (while compensation remained unaltered) was reflected in the number of claims : as the number of claims for incapacity increased, the duration of the cases extended, so that the percentage of claims in each year which lasted for four weeks and over grew larger. It is such factors as these that increase the claims, for "there is no sound evidence of increases in the clinical entity, miners' nystagmus." Definite visible oscillation of the eyes, permanently present when the eyes are above the horizontal level, is the common Continental standard of incapacity. In England compensation may be awarded on a claim "whether the symptom of oscillation of the eyeballs be present or not"; the definition does not distinguish between incapacity due solely to miners' nystagmus and incapacity due to other causes, such as hysteria, etc., in miners who attribute their incapacity to miners' nystagmus.

On the continent miners only stop work for severe attacks; the great majority return to work in a few weeks; anything like a year's absence is quite abnormal. The Committee visited Belgium, where miners' stagnum is looked upon as a benign affection, recovery from which is expected in a short time; yet the cases observed presented the same clinical feature, as those in this country, while men were seen working happily with well marked signs of the disease. When the British and Continental standards were similar our miners worked much as they do now abroad; with the altered British definition, to-day a large and ever-increasing number claim and obtain compensation, many for long periods. Figures are given upon which these conclusions are based.

"The contrast between the length of incapacity on the Continent and in this country challenges attention, and indicates that the economic problem of myasthenia lies far more in an undue protection of disability claims than in the number of original claims." "We have numerous known miners drawing compensation for myasthenia who were incapacitated by such conditions as melanoblastoma, general paresis, syphilis, the insane, various diseases of the heart, leucoparalysis, aggrains, bronchitis, and are injured knee. These men had been able to work notwithstanding the oscillation of their eyes until other troubles appeared." "The standard for certification in vogue in this country undoubtedly lends itself to misuse, and we consider it should be altered."

"We recommend that miners should be considered to have myasthenia sufficiently severe to be certified for compensation if they are unable to work for a period of 12 months."

In the second part of this report are given the refractions in 150 cases of miners' nystagmus and of normal miners. The analysis discloses no relation between errors of refraction and nystagmus: the "errors of refraction in room and using suitable exercises," after it has been induced by darkening the horizontal level, either at or below the horizontal level in daylight, or if it persists for five minutes in a good light with the eyes at the oscillation of the eyes is constantly present even when the miner is subjected to every conceivable form of compensation.

'Second Report of the Miners' Nystagmus Committee, Privy Council Medical Research Council, London: His Majesty's Stationery Office

If the figures of Rehfuess be accepted about 40 per cent. of normal people have hypersecretion, for he found amounts varying from 20 to 120 c.cm. with an average of 50 c.cm. In 1921 Crohn disputed these results, and stated that in the normal the amount was rarely over 30 c.cm., regarding anything above this as constituting hypersecretion, and with this we agree. In the absence of hypersecretion after the stomach is empty very little can be extracted from it, because only a very slow and small secretion occurs in the fasting stomach. This is added to by swallowed saliva and duodenal regurgitation of intestinal contents in unknown amounts, which partially neutralize it. The pylorus allows this to pass out from time to time. Some hours after a meal the resting stomach may thus contain variable amounts of mixed secretions, depending in quantity and composition very largely on the gastric movements, and it may be roughly taken that amounts over about 30 c.cm. indicate hypersecretion. If, however, we simply trust to the amount of resting juice we shall fall into error, because the hypersecretion may not be continuous, but only occur during digestion and for a variable number of hours afterwards; and hence the importance of leaving the tube *in situ* for collection of the juice after the stomach is empty.

With regard to the type of curve during digestion there is only one feature that is suggestive of hypersecretion, and that is a rapid rise in the total chloride curve, with or without a similar rise in the HCl curve in the early stage of digestion when the stomach is full, provided that the organ is not emptying rapidly. The height of the curve later, or whether it falls or rises or remains horizontal, is of no significance for the recognition of hypersecretion. In other words, one is not justified in speaking of a hypersecretory curve; the shape of the curve is determined by the degree of tone of the pylorus. A rapid rise in the HCl curve may occur at the beginning, and a fall as rapid occur due to neutralization, or the curve may be of the climbing type. The contents are watery-looking and copious, the proportion of gruel being smaller than normal. When all the starch has left the stomach the secretion continues in the same amount with the same watery appearance. The analysis of this fluid is interesting. The total chloride curve keeps more or less constantly high. The actual height of the acid curve varies in different cases, but tends to keep constant for the same individual, as the secretion of gastric juice is constant, and the neutralizing process, owing to pyloric relaxation, is also constant for the same person. (Figs. 6, 16.)

During digestion the acid curve may never rise to a high level at all whatever its shape. This is due to a steady regurgitation through the pylorus keeping down the acidity. The hypersecretion is, however, proved by the continued secretion after the stomach is empty or by removing a large amount at this period. In other words, hypersecretion may or may not be accompanied by hyperacidity of the gastric contents. The emptying time is not necessarily altered in either direction by hypersecretion, but depends upon the type of case in which it is occurring. (Fig. 16.)

The gastric juice is normally secreted in response to stimuli transmitted from the central nervous system through the vagi and also to chemical stimuli as the result of the presence of digesting food in the stomach. Hypersecretion originates as an exaggeration of one or other of these two mechanisms. It occurs in irritable conditions of the central nervous system, either primary or induced by abnormal stimulation of the afferent fibres from some portion of the digestive tract. In this case the secretion is characteristically continuous and the fasting juice excessive in amount. If the central nervous system is affected primarily the hypersecretion is liable to occur in spasmodic attacks—so-called periodic secretion.

Hypersecretion also originates during the digestive process as the result of retention of food in the stomach. In these cases the secretion outlasts the emptying of the stomach for a varying number of hours, when it falls off and the resting juice may or may not be present in normal quantity.

The relation of gastric and duodenal ulcer to hypersecretion is not a simple one. The chief effect of an ulcer is

to produce a local spasm in its vicinity; at the pylorus it produces pyloric spasm, in the body of the stomach a ring spasm, and finally obstruction at either point. (Figs. 3, 4, 6, 8.) The effect of this is deficient neutralization and the condition of hyperacidity of the stomach contents in pyloric obstruction, and a similar state of affairs in the proximal sac of an hour-glass stomach. Hypersecretion is finally set up. It is held by some that the ulcer produces a reflex hypersecretion, but if this were so it should occur whether spasm were excited or not and especially in acute ulcer, but this is not the case. When hypersecretion occurs in gastric or duodenal ulcer in the absence of food retention it may equally well be asserted that an ulcer has occurred in a person suffering from gastric irritability and hypersecretion, the latter being a factor in the production of the ulcer. I am inclined to this view, which I expressed in 1915, as the result of my experiments demonstrating the marked influence of HCl in facilitating the formation and delaying the healing of ulcers.

#### DISCUSSION.

Mr. HERBERT J. PATERSON confessed to a strong belief in the value of the old-fashioned test meal. After all, what was needed was a comparison of the working of one stomach with another, and if the test meal was given properly—that is, if the amount and quality of the test meal were uniform, and if it were drawn off at the exact time—it was a most valuable help in diagnosis. He thought the value of test meals was underrated because it was forgotten that chemistry was an aid to but not a substitute for clinical observation. It was useless to send a test meal to a pathologist and expect him to make a diagnosis as the result of his examination. A test meal result must be read in conjunction with the history and clinical examination of the patient. Much more would be learnt if the physician or surgeon examined the test meal himself. The smell and appearance were often such as to suggest carcinoma. Great as was the value of the test meal in diagnosis, it was of even greater value in controlling the diet of a patient after gastro-jejunostomy. It was the only means of determining how far the acidity of the gastric contents had been reduced, and so the only guide as to the nature of the diet which should be allowed. Dr. Bolton's experiments confirmed the view he had advocated for many years—that gastro-jejunostomy was a "physiological" operation. Gastro-jejunostomy reduced the acidity of the gastric contents by allowing the entrance of pancreatic juice into the stomach through the anastomosis. This neutralization might not occur if the stoma were too small or wrongly placed. He was in favour of anterior gastro-jejunostomy because it allowed greater regurgitation of pancreatic juice in the early days after operation; this greater regurgitation occurred, he thought, because in the anterior operation the circular muscular fibres of the stomach were divided to a greater extent than in the posterior operation, and therefore there was less likely to be a sphincteric action at the stoma. If it were true that gastro-jejunostomy was a physiological operation, then excision of the pylorus as a routine measure, as suggested by Dr. Bolton, was unnecessary.

Dr. J. A. RYLE drew attention to certain observations, other than purely chemical observations, which might and should be made in specimens withdrawn for purposes of gastric analysis. These would be particularly of value if the physician or surgeon was able himself to inspect the specimens from his own cases. The resting secretion provided not a little valuable information. In addition to its chemistry, which was subject to great variations, observations might be made in regard to its amount, consistency, naked-eye appearance, odour, and cytology. A clear, limpid, highly acid resting juice in amounts above 50 c.cm., and sometimes above 100 c.cm., was more commonly encountered in duodenal ulcer than in any other condition, and was frequently associated with a clear and copious after-secretion. In conditions of complete achlorhydria, such as occurred in Addison's anaemia, subacute combined degeneration of the cord, and chronic

stomach as a whole. There is a measure of truth in this, but the criticism loses force if care is taken to remove a large specimen from time to time, and it must be further recognized that any method, such as the fractional one, in which the whole of the fasting stomach content is removed before the test meal is given must be far more accurate than the ordinary Ewald technique, in which at the end of one hour a mixture of meal with old and recent secretions is removed and examined, without the observer having any information as to what was in the stomach to begin with.

Even if it be claimed and admitted that the fractional method is the most useful of the present means of performing gastric analysis, it must be acknowledged that cases of serious organic disease of the stomach still occur which baffle detection in this way; the explanation is simple: it lies in the fact that serious organic disease of the stomach may occur without any gross alteration in gastric secretion.

There are, however, certain conditions which are almost invariably demonstrable by careful gastric analysis, and it is my purpose in this paper to deal with one, perhaps the most important, of them—namely, carcinoma of the stomach. My experience leads me to believe that it is exceedingly rare for a case of carcinoma of the stomach to present itself for examination without the diagnosis being definitely established as soon as gastric analysis is performed.

Everyone engaged in the practice of medicine is aware of the importance of early diagnosis in this disease, but certain that very few appreciate the value of gastric analysis in this connexion.

On referring to a number of the most popular textbooks I have been much impressed with the vagueness of much current medical teaching on the subject. There is a lack of agreement between the various writers, and a hesitancy on the part of most of them, that cannot but make the critical reader doubt whether chemical examination is of real value.

Hurst, writing in Price's *Textbook of Medicine*, says: "The absence of free hydrochloric acid (in cancer of the stomach) is of less value, as achylia may also occur with chronic ulcers of the lesser curvature." Poulton, in Taylor's *Practice of Medicine*, says: "In carcinoma of the stomach there is a great diminution in the 'active HCl' and in the amount of 'free HCl'; but this also occurs in some normal people as well as in the group known as achylia gastrica and in pernicious anaemia and acne rosacea." The last edition of Osler's textbook states: "It may be said that free HCl is absent from a large proportion of all cases of cancer of the stomach. Of 94 cases in which the contents were examined, in 84 free HCl was absent. . . . HCl may be absent in chronic gastritis and in atrophy of the gastric mucosa. The presence of lactic acid is regarded as a valuable sign."

These three statements are fairly representative of the teaching accessible to the average English medical student; they cannot be said to foster a belief that there is any great utility in gastric analysis, and the main impressions they convey are, first, that in most, but not all, cases of gastric cancer, there is no free HCl in the gastric contents; and secondly, that this is similar to what is seen in cases of chronic gastritis, pernicious anaemia, and achylia gastrica.

I believe that I have stated this fairly, and it is certainly the impression that is left after reading accounts in a large number of textbooks, both English and American. I do not, however, believe that it at all conveys the opinion of those who have actual personal experience of gastric analysis, and I can myself state, as the result of prolonged personal investigation, that free HCl is secreted by the stomachs of the majority of patients suffering from gastric carcinoma, and that, even when a patient with gastric carcinoma has complete achlorhydria, the gastric analysis is rarely identical with that given by a patient with pernicious anaemia, chronic gastritis, or any other form of "benign" achylia. Two examples will illustrate this.

#### CASE I.

J. L., male, aged 53, was admitted to Middlesex Hospital in January, 1923, under the care of Dr. A. F. Voelcker, by whom I was asked to perform gastric analysis. The patient gave a five weeks' history of dyspepsia, unrelated to food; he had on six occasions vomited profusely; visible peristalsis was present. There was a history of syphilis, but the Wassermann reaction was negative. A glass of milk containing  $1\frac{1}{2}$  drachms of powdered charcoal

was given overnight, and a modified Einhorn tube was swallowed at 9.30 on the following morning. Over a pint and a half of sour-smelling fluid, containing much charcoal, was recovered; no free HCl was present in this; the total acidity was 50. The stomach was then repeatedly washed with water, and the washings at the end of a quarter of an hour contained free HCl 10, total acid 35. It being clear that pyloric obstruction was present, laparotomy was performed three days later by Mr. C. H. S. Webb; a small early carcinoma was found, causing such obstruction that when water was placed in the stomach after excision drops only could be made to traverse the pylorus, though a finger could be readily introduced from the duodenal side. Histological examination confirmed the diagnosis of carcinoma; the main surface of the stomach was normal.

This case illustrates (1) the rapid onset of pyloric obstruction in many cases of gastric carcinoma; (2) the operability of many such growths; (3) that the inhibition of normal secretion may be due mainly to coating of the mucosa with retained products; (4) the production of free organic acids by fermentative bacteria above an obstruction. An Ewald test meal or an ordinary fractional gastric analysis would certainly have shown in this case (1) an absence of HCl just as in a non-secreting achylia gastrica; or (2) a high total acidity quite different from the low total acidity of pernicious anaemia and achylia gastrica.

#### CASE II.

C. G., a man aged 60, Hospital under the care of Dr. Essex Wynter, 1922. For two months he had had vague dyspeptic symptoms recently enhanced by shooting pains radiating towards the lumbar region some two hours after food. He had never vomited; the appetite was very poor; no tumour was palpable; he was somewhat pale and wasted.

The fractional gastric analysis is shown in Fig. 1, and at first sight suggests the picture of achylia gastrica, such as is seen in pernicious anaemia, chronic gastritis, etc. It differs from such a picture in the following essential particulars: the fasting stomach contained 15 c.cm. only, but there was a faint sour smell, traces of charcoal taken the previous evening were visible, as well as very definite amounts of blood, both fresh and "coffee-ground." The specimens removed from the stomach at one hour and one and a half hours also showed blood. No free HCl was discoverable at any time, but though the total acidity was low, that of the fasting content was 18, which is higher than is seen in benign achylia. These findings pointed clearly to a lesion producing some stagnation, though it could hardly be called partial obstruction, together with haemorrhage from the stomach, and diagnosis of carcinoma was made, which was fully confirmed by the subsequent history of the case.

FIG. 1.—Fractional gastric analysis, carcinoma ventriculi. The blood, charcoal, and relatively high total acidity of fasting content distinguish it from cases of benign achylia gastrica.

#### The Positive Diagnostic Picture.

My protest against current teaching would have very little value if more positive evidence were not obtainable; that such evidence is forthcoming has been shown in the cases cited and may be summarized in the following statement:

If the patient be suitably prepared overnight, and if careful examination of the contents of the fasting stomach be made the following morning, evidence either of stagnation, or of haemorrhage with aberrant secretion, or of both, will be found in the vast majority of cases of gastric carcinoma, and these signs are not likely to be confused with those given by other diseases.

I have tried to express this in terms commonly used by clinicians, for much of the confusion existing on this subject is, I believe, due to results being stated in purely chemical terms. The biochemist is too often asked to make a report on a specimen removed from a patient whom he has never seen and of whose clinical state he is entirely ignorant; his reports in consequence tend to become technical statements written from a point of view very different from that of the clinician, and omitting data which are of small chemical importance but possibly of immense significance in a clinical inquiry. For example, reports of gastric analyses often contain the information that little or no free HCl was present, but much lactic or organic acid; the fact that this is evidence of stagnation, of bacillary fermentation above a partial obstruction, is not alluded to; the chemist is not always aware of the deduction, the clinician fails to make it.

must be the introduction of reasonably sufficient water supplies where these have been deficient. Farmers and their employees have not been distinguished by any special receptivity of new ideas, and the reader of Mr. Lattick's little treatise may speculate as to what a country cowkeeper who died twenty or thirty years ago would, if he could now revisit the earth, think of all the wonderful developments that have taken place since his departure. The terminology would confound him—bacteria, coliform bacilli, agar plates, Petri dishes, the counting of colonies, and so forth! Having puzzled and groaned over these, he would probably be glad to creep back into his coffin.

doing so.

medical qualification, and instead of having a Parliamentary Under Secretary to deal solely with health Scotland, his time and attention to this most important duty. At the time of the creation of the Board of Health the Scottish Committee of the British Medical Association had a good deal of negotiation with the then Secretary for Scotland, and the above-mentioned points were conceded as a result of the representations made. Their withdrawal now comes near to being a breach of faith, and is certainly a rebuff to the profession and a lowering of the status of medical service. The Scottish Committee will no doubt protest, and will probably join with other bodies in

The very nature of the criteria by which success or failure in milk competitions is determined ought to command them to all concerned. In judging a cow or a horse, and in awarding or withholding a prize, the individuality of the judges and their views about points of excellence may presumably vary, so that their verdict may not always be approved by the losers, or even by spectators. But in milk competitions there are accepted standards of value; tables in which the points to be allowed for every detail are published for general information, so that there should be much less room for difference of opinion than in the verdict of the referee at a boxing match which has not been decided by a knock-out. In milk competitions the score card system, introduced by the National Clean Milk Society, was expanded and adopted by the Local Government Board during the war, and is now well established and understood. In a total of 125 possible marks, which would be a "perfect score," a minimum number of colonies of bacteria per cubic centimetre counts 39, the absence of coliform bacilli 18. In food value fat is assessed at 29, solids not fat 8, flavour and odour 20, while the best figure for the absence of visible dirt is 6, and for the condition of the container 5. In this summation it is good to observe the place held by food value. The assessors have not been carried off their feet by the bacteriologists, but have thought of sustenance as well as of purity, so that the slimmest of dairymen cannot in this competition make purity a substitute for substance, whatever he may risk doing in his daily rounds. In this fashion the most modern of sciences has invaded the sphere of the morning milkman, and it is safe to say that the children of the country are reaping a daily benefit.

#### THE SCOTTISH BOARD OF HEALTH:

##### A RETROGRADE STEP.

Our review of the parliamentary session in last week's closing days of the session of the Reorganization of Offices (Scotland) Bill, which was ordered to be printed on July 30th. The Scottish Board of Health Act, 1919, provided for the appointment of a Parliamentary Under Secretary for Health and for the constitution of a Board of Health of six members, one of whom must be a registered medical practitioner. The bill now introduced proposes to abolish the former office and to appoint a Parliamentary Under Secretary for Scotland, and it proposes further to limit the number of members of the Board to three, and, most important of all, it abolishes altogether the qualifications of members. The result will be that health matters in Scotland will be administered by a Board none of the members of which need have any

## SOME APPLICATIONS OF PHYSIOLOGY TO MEDICINE.

### II.—VENTRICULAR FIBRILLATION AND SUDDEN DEATH.

BY

J. A. MacWILLIAM, M.D., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.  
(From the Physiological Laboratory.)

(Concluded from page 219.)

#### *Sudden and Unexpected Death during Rest.*

THE difficulty of explanation of such deaths has long been felt, in the absence of recognized conditions (effort and excitement) tending to make an extra call on the heart and of such powerful afferent excitation as might be assumed to be provocative of reflex inhibition of intensity and duration sufficient to be fatal. Recourse has constantly been had to the verdict of "failure of the heart's action," though the sudden collapse in cardiac efficiency remains unaccounted for, *post-mortem* examination often affording no explanation of the abrupt ending of life. Sir Clifford Allbutt,<sup>27</sup> while suggesting vagus inhibition as a mode of death during anginal attacks, writes with regard to the class of deaths now under consideration—during conditions of rest, apart from anginal attacks, and where no exciting cause is apparent:

"But the riddle, which I have done so little to read, is the frequent suddenness of death in one who, having scarcely known illness, expires under no extraordinary effort; or in the peace of his own bed or chair passes silently away. The reading of this riddle is not yet."

In this relationship the facts that have been stated with regard to the more or less remote effects of experimental interference with the coronary blood supply by ligation of a branch are obviously of profound significance, showing as they do that ordinary life can go on for prolonged periods (months), either with or without signs of cardiac disturbance, until a sudden ending comes by fibrillation, sometimes during muscular effort, but often apart from this, in the absence of recognizable exciting cause or in presence of causes too trivial to have any effect under ordinary conditions. And, apart from sudden obstruction, there is no reason to doubt that a gradual interference with the blood supply as a result of coronary disease can, by damaging the nutrition and altering the properties of the muscle, lead to an abnormal susceptibility to fibrillation.

The applicability to man of these results is naturally easy in view of the widespread tendency to serious impoverishment of the blood supply (local or general) of the cardiac muscle in the later half of life, the period when deaths of the class under consideration usually occur. In the light of these facts we have a rational basis for many unexplained disasters—fatal events that otherwise remain shrouded in mystery.

While the effects of limitation of the blood supply are proved by abundant and convincing evidence, other agencies, such as perverted nutrition, toxic influences, generative changes, etc., can be effective causes. Interference with normal functioning of the Purkinje fibres on the inside of the ventricles comes into question as well as alterations in the ordinary myocardium. Fibrillation may be determined at a certain point of time by a sudden aggravation or cumulation of the toxic condition, etc., aided, it may be, by the incidence of some disturbance of the vascular system too slight to produce any serious effects except in the specially predisposed condition.

It is to be borne in mind that the conditions disposing to and leading up to fibrillation need not pervade the whole of the ventricular musculature, but may be limited to a certain amount of that tissue, as after obstruction of a coronary branch and in other conditions; changes in restricted areas can set up fibrillation, which involves the rest of the muscle, healthy as the great bulk of it may be. It is readily intelligible that such limited changes may naturally be associated with little or no recognizable altera-

tion in the force of the ventricular beat or its general efficiency. Thus there may be little or no warning of the impending catastrophe, even at a time when the mine has been laid and only a spark is needed to precipitate the explosion.

#### *Abnormal Cardio-vascular Variations of Obscure Origin.*

Under certain conditions of cardio-vascular instability—usually occurring in association with morbid states of the arterial system—irregular tides of circulatory change, often obscure as regards their exciting causes, are sometimes recognizable; one manifestation of these is found in the extensive variations of arterial pressure as measured under similar conditions from day to day or at shorter intervals. These variations are sometimes, but not necessarily, associated with discrepancies in the sphygmomanometer readings from different limbs, depending on local causes—the presence or absence of strong contraction in the large arteries of the respective limbs. Actual rises of general arterial pressure involve cardiac changes in addition to vascular constriction, etc. It is evident that disturbances of this kind may be influential with regard to the onset of anginal attacks or of sudden death in subjects where a special predisposition exists.

#### *The Question of Coronary Spasm.*

With regard to sudden interference with coronary blood supply, apart from the rare accident of embolism and the less rare occurrence of thrombosis, there arises the question of spasmodic contraction—an old hypothesis as applied to the explanation of anginal attacks. The obscure cardio-vascular disturbances already referred to might be invoked to account for the onset of some anginal attacks during rest; the attack might be determined by antecedent unrecognized changes in blood pressure and heart action. But there are on record cases in which such attacks during a period of rest are found to be unattended by elevation of the blood pressure or recognizable changes in the heart's action. Again, there are instances among anginal subjects who have varying periods of relatively low and high pressures, where no greater tendency to angina has been found in the phases of high pressure; a notable example of this has been recorded by Sir James Mackenzie. In such cases the idea of coronary spasm has commended itself to many observers, supported by such analogies as the extreme arterial constriction of Raynaud's disease, the thickening and narrowing of the temporal artery on the same side as the pain in migraine and the occasional association of Raynaud's disease and migraine, the occurrence (sometimes in relatively youthful subjects) of transitory aphasias, hemiplegias, etc., attributed to an acute temporary anaemia or ischaemia from extreme constriction of a cerebral artery, and sometimes associated with migraine. Again, there is the so-called "abdominal angina," which has been correlated with spasmodic contraction of sclerosed mesenteric arteries. Sir William Osler,<sup>28</sup> referring to arteries in general, states that in a certain stage of sclerosis arteries are very prone to spasm—a view repeatedly urged by Professor W. Russell<sup>29</sup> and supported by Pal<sup>30</sup> and many others.

It is evident that a temporarily excessive contraction of some part of the coronary system (especially in cases where the blood supply is already reduced or minimal) would induce an ischaemic condition which might be responsible for the onset of fibrillation or of an anginal attack; in this way an apparently unprovoked paroxysm of pain during rest might be accounted for and also its equally unexplained passing off after variable periods. It might also be surmised that amyl nitrite may relax a constricted coronary as part of its general vascular effect, with relief of pain which may last after the general blood pressure has again risen to its former level. The spasm hypothesis has been subjected to searching criticism by Sir Clifford Allbutt, who among many other considerations states that amyl nitrite gives no relief in transitory hemiplegias and aphasias. There is also the occurrence of dyspnoea in coronary obstruction from sudden thrombosis or embolism (as established *post mortem*) and its absence as a necessary feature of typical angina; but a possible explanation of this difference can be suggested.

THE LOOMIS SANATORIUM, NEW YORK.

The twenty-sixth annual report of the Loomis Sanatorium, New York, affords a comprehensive account of the year's work. Complete tables are given relating to the number of patients, their stage of disease, the complications encountered, the cause of death, their place of birth, their place of residence, their sex, age, occupation, social condition, religious denomination, and state on discharge, but no information as to the presence or absence of tubercle bacilli in the sputum, or of any specific treatment—such as artificial pneumothorax or tuberculin—which may have been adopted. Of the 199 patients considered on admission were in the incipient stage of the disease, 50 per cent. in a moderately advanced stage, and 42 per cent. in a far advanced stage. Of these 3 per cent. were discharged arrested, 4 per cent. apparently arrested, 34 per cent. quiescent, 23 per cent. improved, and 20 per cent. unimproved; 16 per cent. dead. These results, however interesting in themselves, are hardly to be compared with figures as those in the Addenbrock or Midhurst reports, as the proportion of advanced cases is so very much higher in the Loomis Sanatorium, which, as is stated in the prospectus, is designed "for the care of tuberculous invalids presenting a fair prospect of recovery," not as in the case of most sanatoria, for the treatment of patients with incipient disease. Several pages of the report are devoted to a record of the patients treated since the foundation of the sanatorium in 1856, with tables showing the number of inquiries sent out, the number of replies received, and the state of health of those patients who are still living. As, however, no data are provided giving the number of patients who have died in the meantime, the value of the figures is small. It is of little interest, for example, to know that of the former patients reported to be alive, 85.45 per cent. are in a satisfactory condition of health, if we do not know at the same time what percentage of patients has survived at all. Attached to the sanatorium is a research laboratory in which work has been undertaken on problems connected with tuberculosis. It has been found that there is an inverse correlation between the blood lipase content of the patient and the excellency of the prognosis. Those cases with a low lipase content present but poor chances of recovery. More and more reliance is being placed upon the Roentgen rays, and especially on stereographic photography—a method, we believe, destined to play a part of increasing importance in the assessment of the extent of disease and of its alterations during the course of treatment. The report, as regards its production and illustration, upholds the best traditions of the Americans, and we would recommend it to all who are interested in the sanatorium treatment of tuberculosis.

INTERNATIONAL UNION AGAINST TUBERCULOSIS.

The Council of Directors of the International Union against Tuberculosis held its annual meeting in Paris on July 26th last, at the headquarters of the League of Red Cross Societies. Twenty members of the council from different countries met under the presidency of Dr. Devez of Brussels. Professor Léon Bernard, Secretary-General of the Union, gave an account of the development of the Union since the Brussels conference. It was decided that the following questions should be placed on the agenda of the conference to be held at Lausanne in September, 1924: (1) What are the relations between pregnancy and tuberculosis? To be reported on by Professor Forester (Stockholm). (2) Do there exist naturally or can there be produced artificially saprophytic forms of Koch's bacillus which might become virulent tuberculosis bacilli? Report by Professor Calmette (Paris). (3) What are the effects of the

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS.

We publish in the *STRAIGHTENERS* this week (pp. 110-111), at the request of the Registrar of the General Medical Council, a list of the names of those medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. The list now published includes all untraceable names from H to O in the body of the *Medical Register*, as it is only this section that has come under review in the present year; since it was prepared many further inquiries have been made by the Registrar. Any medical practitioner who finds his or her name included in this list should communicate at once with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1.

We much regret to learn of the death, on August 10th, of George Edward Rennie, M.D., F.R.C.P., physician to the Royal Prince Alfred Hospital, Sydney. Dr. Rennie was at one time Editor of the *Australian Medical Gazette*, and for some years was a valued contributor to our columns. We hope to publish an obituary notice in a future issue.

The usual half-yearly indexes to the *JOURNAL* and to the *STRAIGHTENERS* are now published; they will be issued only to those readers who ask for them. Any member of the British Medical Association, 429, Strand, W.C.2, can obtain what he wants, post free, by sending a post-card or subscriber who desires to have one or all of the indexes notified his desire to the Financial Secretary and Business Manager.

themselves or transmitted with abnormal frequency from the auricles as in auricular flutter—that the ventricles can stand without fibrillating varies much in different conditions; when the conductivity is already depressed and the conduction time long, a much lower grade of acceleration naturally suffices to establish fibrillation, as can be demonstrated experimentally.

From the work of many observers we know that in certain hearts (for instance, after coronary ligation, etc.) there is often a characteristic sequence of events illustrative of the close relations of tachycardia and fibrillation—extra-systoles, first singly, then in irregular runs, more or less continuous tachycardia, and finally fibrillation. Apart from the super-vention of fibrillation it is known that the fall of blood pressure attendant on tachycardia is compatible with life for very considerable periods; there have been recoveries after periods of excessively low blood pressure attended by unconsciousness, etc., for hours. It remains to be seen whether the fall of blood pressure is often or ever sufficient *per se* to kill, or whether the fatal issue is always determined by the occurrence of fibrillation. There are no grounds for accepting vagus inhibition as a mode of sudden death during tachycardia. The vagus is known to lose effectiveness in this condition. Auricular flutter, etc., may induce unconsciousness lasting for hours without causing death; a very small blood supply can suffice to keep the nerve centres alive, as Leonard Hill showed many years ago. The absence of fibrillation is an essential feature in the recovery from ordinary cases of fainting due to temporary vascular relaxation due to vasomotor failure or to vagal inhibition, etc.

#### *Status Lymphaticus, Electrical Shock, Digitalis.*

A possible development of the mechanism of fibrillation is worthy of consideration in connexion with the sudden and unexplained deaths of the status lymphaticus, occurring, as they often do, in the absence of any recognized causation. The features of some recorded examples would fit in with the known phenomena of fibrillation—for example, such cases as have shown an abrupt abolition of the signs of heart action while the respiratory movements persisted for some little time, in marked contrast to the order of events in death by asphyxia.

Fibrillation is one of the modes of death in electrical shock, and according to Jex-Blake<sup>32</sup> it is operative in death from lightning. There is convincing evidence—experimental and clinical—that the same mechanism is responsible for sudden death during overdosing with bodies of the digitalis series.

#### *Sudden Death in Aortic Regurgitation.*

The frequency of absolutely sudden death in this condition has long been recognized. In view of the usual coronary and myocardial involvements, the causation of the fatal issue—sometimes occurring without antecedent signs of cardiac failure—may naturally be ascribed to ventricular fibrillation. There seem to be no good grounds for the assumption of protracted vagus inhibition as an effective cause.

#### *Reflex Cardiac Inhibition.*

Reflex vagus inhibition has in the past been freely invoked to account for sudden death in many diseased conditions and even in healthy persons—for example, from a violent blow on the epigastrium, etc. On the experimental side extended investigations on a great number of healthy animals and a considerable number of diseased ones have failed to lend support to the hypothesis: it has usually been found impossible to stop the heart long enough to kill by reflex inhibition or even by strong direct stimulation of the vagus, escape of the heart or the ventricles usually occurring much too soon for death to be caused by circulatory arrest. The conclusion has been reached by different observers that the possibilities of a fatal issue in this way have, to say the least, been greatly exaggerated, and that there is no sufficient ground for assuming reflex inhibition *per se* to be a frequent or important mode of death.\* In some instances

where the vagal hypothesis had met with a large measure of acceptance—for example, in cases of sudden death during an early phase of ordinary chloroform anaesthesia—the view has not proved to be tenable, since such deaths have been shown to be essentially due to an altogether different mechanism—ventricular fibrillation.

On the other hand, the possibility of increased susceptibility to vagus inhibition under certain abnormal conditions must be borne in mind. In Embley's<sup>36</sup> work on chloroform it was found that under special conditions, in dogs after a large dose of morphine, the inhalation of strong chloroform vapour may cause great slowing of the heart, fall of blood pressure, and stoppage of respiration—consequences evidently depending on excessive vagus action, and obviated or removed by exclusion of such action by section of the vagi or by atropine. But the conditions present in these experiments differ widely from those of simple chloroform anaesthesia as ordinarily conducted in man. It is well known that in dogs morphine tends to exaggerate the controlling influence exercised by the vagus centre over the heart.

In Laslett's<sup>37</sup> well known case it was clear that vagus inhibition induced repeated syncope attacks, causing cardiac standstill of the whole heart, sometimes lasting for periods of six to eight seconds, but not long enough to cause death; atropine was found to be effective as a counteracting agent.

In this connexion certain observations by Sir Hugh Anderson, cited by Sir Clifford Allbutt,<sup>38</sup> are very noteworthy. These were on cats in which the cardiac augmentor nerves were cut, by the stellate ganglia being excised some time previously. It was found that swinging the animal in the air caused pronounced slowing of the heart—for example, from 120 down to 40 in the case of old cats.\* (It may be remarked that such degrees of slowing were not at all dangerous, and probably did not even cause much lowering of the systolic blood pressure.) But a remarkable tendency to sudden death was observed in these animals. No evidence is stated to show whether such deaths were actually due to extraordinarily prolonged cardiac standstill, or to the supervention of some other change—for example, ventricular fibrillation, to which cats are known to be specially prone under various conditions. So far as the available evidence goes, there is nothing to indicate that the observed slowing was more threatening to life than similar slowing as seen often in common cases of non-fatal syncope in man.

With reference to possible applications of indications afforded by such experiments to the human subject it has to be remarked that we know of no clinical condition in man where there is reason to believe that conditions at all resembling those stated above are ever present—consequences of an interruption of the various paths that traverse the stellate ganglia, loss of the nerve cells contained in them, etc.† Experimental investigation shows that the cardiac augmentor nerves are very persistent in their action, extremely resistant against drugs and various abnormal conditions, and demonstrably capable of strikingly effective action in many gravely depressed states of the cardiac muscle—in contrast to the vagus functions, which are well known to be readily diminished or cut out altogether by various chemical agencies, etc.

In many cases of common syncope vagus slowing of the heart down to 50, 40, etc., a minute is a feature, but such slowing is wholly insufficient to account for the fall of blood pressure and the loss of consciousness; there are other factors concerned. Such cases do not have a fatal issue. Some instances of this condition were described by Lewis<sup>39</sup> a few years ago in subjects of "irritable heart." Pretty extensive cardiac slowing is quite compatible with a fairly

\* Sir Clifford Allbutt predicated an increased potency of the vagus in old and damaged hearts. Gilbert (*Arch. of Int. Med.*, 1923, xxxi, 423) has recently found in old people a more ready response of the vagus to digital compression—an age effect, apart from pathological cause. The mechanism of digital pressure is undecided—whether it acts directly by stimulation of afferent (inhibitory) fibres or reflexly by excitation of afferent fibres. There seems to be no proof of actual danger to life in this way.

† Jonnesco's operation for angina pectoris is an example, resection of the lower cervical and the first thoracic sympathetic ganglion being done with the object of interrupting afferent paths from the heart. Jonnesco recommends the bilateral operation, regarding it as harmless; he does not seem to have recognized any such dangers as were noted in Anderson's experiments. (Jonnesco, *Bull. de l'Acad. de Méd.*, Paris, 1920, lxx, 53; *Presse Méd.*, 1921, xxix, 193; *Ibid.*, 1922, xxx, 353.)

\* Sudden death during operative procedures in the thoracic cavity (thoracocentesis, etc.) seems, in the light of the work of Capps and P. D. Lewis, to depend on fall of blood pressure due to vasomotor changes rather than to reflex cardiac inhibition (*Arch. of Int. Medicine*, 1907, cxxvii, 868).

body; the contents are merely unsaleable, but may be used for confectionery after proper boiling. The essential requirements to prevent unsoundness are that the heating before condensation shall be sufficient to kill yeasts; that in cooling, condensation should be attended to; the final

condensing condensed milk are unscrewed and cleaned with

Although several weeks before being released for distribution, the report states that the presence of lactose fermenting bacteria in the milk is deemed as soon as possible; and that only airtight tins are used. Each batch of milk to be kept in a water special room for several weeks before being released for distribution.

members of the *D. coli* type or of remaining yeasts in the gram or less suggests unsatisfactory conditions which might rightly warrant the rejection of an individual tin and would serve to direct attention to the methods of manufacture with a view to their critical inspection.

*Methods of Manufacture.*

growth, but chiefly to the restricted supply of oxygen. In

pasteurized and become unsalable. Before condensation the milk is cooled down rapidly to prevent further bacterial growth and increase of acidity, and to allow the milk to be supplied hot to the consumers. During condensation the milk is boiled under reduced pressure until the desired consistence is reached, then cooled and put into cans. The cans are passed through a machine which fills them with a quantity of each can. The tops are on by hand and rendered airtight by a machine. The sealed tins are then placed in a retort and heated to temperatures of 110° to 116° C. for thirty to forty minutes. Heat penetration is facilitated if the tins are rotated during sterilization. They are cooled rapidly by the admission of water to the retorts. Processed tins are usually stored only after careful checks and passed for labeling and marketing.

## II. UNSWEETENED CONDENSED MILK.

The yeasts may be derived from the original milk, the air of the factory, or a deposit in the vacuum pans. After the milk has been pasteurized it is once again heated to a temperature high enough to ensure destruction of yeast cells.

*Bacteriology of Unsweetened Condensed Milk.* Examination of sound shop and factory samples showed about 80 per cent. sterile; the non-sterile tins contained from 10 to 100 million bacteria per tin. The results of laboratory tests recorded in this report showed a fairly close correspondence between external physical defects and the condition of the contents. The present methods of examination are satisfactory and reliable, and the opening of a few tins will usually clear up any doubtful points.

*Bacteriology of Unpasteurized Condensed Milk.*

The first of these is the fact that the world is not a uniform whole, but a collection of many different parts, each of which has its own characteristics and its own laws. The second is the fact that the world is not a static whole, but a dynamic whole, which is constantly changing and developing. The third is the fact that the world is not a simple whole, but a complex whole, which is made up of many different elements and forces. The fourth is the fact that the world is not a single whole, but a many-whole, which is made up of many different parts, each of which has its own characteristics and its own laws. The fifth is the fact that the world is not a uniform whole, but a collection of many different parts, each of which has its own characteristics and its own laws. The sixth is the fact that the world is not a static whole, but a dynamic whole, which is constantly changing and developing. The seventh is the fact that the world is not a simple whole, but a complex whole, which is made up of many different elements and forces. The eighth is the fact that the world is not a single whole, but a many-whole, which is made up of many different parts, each of which has its own characteristics and its own laws. The ninth is the fact that the world is not a uniform whole, but a collection of many different parts, each of which has its own characteristics and its own laws. The tenth is the fact that the world is not a static whole, but a dynamic whole, which is constantly changing and developing. The eleventh is the fact that the world is not a simple whole, but a complex whole, which is made up of many different elements and forces. The eighteenth is the fact that the world is not a static whole, but a dynamic whole, which is constantly changing and developing. The nineteenth is the fact that the world is not a simple whole, but a complex whole, which is made up of many different elements and forces. The twentieth is the fact that the world is not a single whole, but a many-whole, which is made up of many different parts, each of which has its own characteristics and its own laws.

decomposes the contents. Probably the presence of anaerobes. Gas-forming aerobic bacteria were not found in any sound samples. *B. coli* and *B. steiriae* can grow in and decompose unwatered milk. These organisms are therefore a definite cause of taints clored. Gas development in unwatered milk is of no consequence, but fermenting types are of no consequence. Non-fermenting bacteria are rarely present. Fermenting types may cause bloating of cans. Thermophilic bacteria are rarely present and of no significance. Mesophilic bacteria are rarely present and of no significance. Gas production, Coccidial bacilli (small), cane acid, clothing, and non-motile, non-sporing Gram-positive bacilli are capsulated.

and sudden close from failure of cardiac function, occurring often in persons whose hearts are far from being worn out, but on the contrary are endowed with myocardial power amply sufficient not only for quiet existence but not infrequently for the demands of considerable bodily and mental activity.

There is reason to believe that in man, as in animals, an undue susceptibility to fibrillation is sometimes a temporary phenomenon depending on circumstances that may be more or less markedly transitory, though no doubt it is very often a persistent condition depending on abnormal changes in the ventricular musculature; in the latter case immunity from sudden death must in large measure depend on avoidance of the directly provocative causes of fibrillation in a predisposed heart, such as sudden muscular exertion, especially when accompanied by emotional stress, etc.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## UNUSUAL VARIETY OF "SORE THROAT."

are frequently met with in which sensations of or discomfort in the pharynx are complained of but cause can be found on physical examination. It has been recognized that the styloid process may project to the tonsil even to such an extent as to form a projection in the lateral wall of the pharynx. This elongation is probably due to ossification extending down the stylo-hyoid ligament, but has been regarded as an anatomical curiosity rather than as of clinical importance. I have recently met with two cases in which this condition gave rise to symptoms which were entirely relieved by removal of a portion of the bony process.

A woman, aged 30, had for two weeks suffered discomfort and dragging sensation in the left side of the throat, especially on swallowing. There had been no previous throat symptoms. An ill defined projection of the lower pole of the left tonsil could be seen, and the patient had herself discovered this hard "knob" with her finger, and ascribed her sensations to this situation. Under a general anaesthetic an incision was made through the anterior pillar of the fauces, the bony process freed, and three-quarters of an inch removed with bone forceps. The wound was sutured and recovery uneventful.

A woman, aged 37, had had pain in the left side of the throat for three months. On examination a similar condition was found to that existing in the previous case, and here also the patient had herself discovered the hard swelling. A similar operation was performed, during which it was found that the styloid process on the right side was also elongated and palpable, but to a less degree. This was not interfered with.

In addition to these two cases, I have collected eight others from the literature. Of the total of 10 cases, 7 were females, only 3 males. The ages ranged from 23 to 55. In 7 of the cases the left side was involved, and in 2 an elongated process could be felt on both sides, but only gave rise to symptoms on one. The period during which symptoms had been noticed varied from a fortnight to ten years, with an average of three years. In all cases the symptoms were very similar, consisting of discomfort and dragging sensation in one side of the throat, most marked on swallowing and sometimes on talking. In some of the cases there was a history of previous attacks of tonsillitis. Trauma as a possible factor was present in one case, symptoms being first noticed after a violent blow on the head. Nine of the 10 cases were submitted to operation, with relief of symptoms in every case. In some of the cases the tonsil was removed in addition to the portion of the styloid process, but the results seem to have been equally good where this was not done.

Details of the various cases are given in the *Journal of*

*Laryngology*, 1915, pp. 116, 176, and 303; the *Laryngoscope*, November, 1915, November, 1918, and May, 1920; and in the *Journal of Ophthalmology, Otology, and Laryngology*, May, 1917.

## THE CAUSE OF "STITCH."

"STITCH" is a very common condition among adolescents; it is a very severe pain, felt generally at the costal margin on one side; it is brought on by running or riding, and ceases at once when the pace is reduced to a walk. There is another "stitch," which is felt above the clavicle on one side, in the same circumstances; this is much less common than the subcostal type.

There are two possible causes for "stitch": stretching of pleural or peritoneal adhesions, or interference with the action of the diaphragm by gas in the stomach or colon. The condition seems to me to be too frequently met with to be due to pleural adhesions, since these are not very common in young subjects.

I recently saw a boy, aged 12, who, when he ran, always got "stitch," generally below the left costal margin; he had become so much worse that he had lately been compelled to sit down after walking a few hundred yards. He had had tuberculous glands in the neck, so that the existence of pleural adhesions was quite a reasonable assumption in his case; but I was struck by finding extreme tympany in the splenic region. He was habitually constipated, as many boys of his age are. Thinking that the gas was probably in the splenic flexure I gave him a short course of grey powder, and a prolonged course of dimol. In three days he was able to walk and run without any suspicion of "stitch"—a thing he had never been able to do before. But he gets recurrences if he leaves off the dimol for more than a few days.

## ACTINOMYCOSIS OF THE RIGHT ILIAC FOSSA.

The case here reported is of interest, not only owing to its rarity, but also because it demonstrates how few symptoms may be present in such cases.

A boy, aged 12, was admitted to the Southend Victoria Hospital at the end of March with a large swelling in the right iliac fossa. He stated that a week previously he had been kicked in this region whilst playing football. Three days later he noticed a swelling, which later on became tender. He felt unwell. There had been no vomiting nor acute pain. He was not constipated. The boy was pale, thin, and looked ill; the temperature was 99.4°, and the pulse 94. There was a large fluctuant, tender swelling in the right iliac region, and the diagnosis of an abscess resulting from infection of a haematoma of the anterior abdominal wall was made. The abscess was incised and packed with flanne gauze; during the next month it healed, leaving a small sinus. The boy put on weight rapidly; the temperature, however, remained persistently high (103° at night, 99° in the morning) and was not affected by vaccine therapy.

Mr. Maingot found that a probe could be passed down the sinus into the right iliac fossa; its passage was followed by escape of offensive pus showing typical sulphur granules, which microscopically proved to be actinomycetes. For the next month intensive treatment with potassium iodide was employed; the sinuses were also excised. The temperature was quite unaffected, however, and after a month it was again considered advisable to explore the right iliac fossa, as the condition of the boy had become very serious. At the time of operation a hard mass was found in the right iliac fossa, but there was no evidence of the pus having tracked towards the kidney or diaphragm. The boy unfortunately was in such a weak condition that he died under the anaesthetic. No post-mortem examination could be made. It is of interest that the temperature was not affected by potassium iodide; this was possibly due to a secondary infection being present.

I am indebted to Dr. Cleveland Smith for permission to publish this case.

## MATERNITY DEPARTMENTS IN MANCHESTER.

A clinical report of the Maternity Department of the St. Mary's Hospitals, Manchester, for 1921 has been prepared by Dr. John W. Braid, the honorary assistant obstetric surgeon and registrar, and Mr. Frank S. Horrocks, M.B., Ch.B., the resident obstetric officer.

It appears that the total number of cases treated by the hospitals during the year was 2,560; of these 1,446 were treated in their own homes; a decrease of 216 on the preceding year; owing to an epidemic of scarlet fever in the early part of the year the hospital was closed for a month on the advice of the local authority. All cases, whether normal or abnormal, in the district are seen by the medical officers. It does not state whether the early examinations are carried out in the homes of the patients or whether antenatal clinics are held which the patients are invited to attend. The maternal mortality for the 1,544 patients admitted was 45 (2.9 per cent.). The hospital admits serious cases from outlying districts and no one is refused if room can be made. Many of the cases are sent in by practitioners after attempts at delivery have failed. The maternal mortality was 97 (6.3 per cent.). The standard adopted for the estimation of morbidity is as follows:

A rise of temperature (during the first eight days of the puerperium) exceeding 100° occurring twice within 24 hours, irrespective of the pulse rate, and excluding the first 24 hours after delivery.

Among the 1,544 cases admitted there were 17 cases of twins, 28 occipito-posterior positions, 42 breech presentations, 26 transverse, 24 prolapse or presentation of funi, and 13 brow and face; abortions complete and incomplete numbered 276, and there were 4 cases of hydatidiform mole. There were 43 cases of placenta prævia, 2 mothers died and 26 children were stillborn; there were 27 cases of accidental hæmorrhage, one only of the concealed type; 19 of the children were stillborn; there were 8 cases of severe post-partum hæmorrhage, with 3 maternal deaths. Out of 119 cases of contracted pelvis treated in the hospital 4 were delivered by forceps, 7 by craniotomy, 99 by Caesarean section, and in 9 cases labour was induced. Of the cases in which Caesarean section was performed 9 were sterilized. Thirty-seven cases of eclampsia were admitted; of these 11 died. Twenty-three cases of ectopic pregnancy were operated upon and all made good recoveries. The deaths among children in the hospital, including premature children, numbered 216; of these, 95 full-term children and 90 premature were born dead; the remainder died after birth.

A considerable amount of teaching is given at the hospital; during the year 81 students, 11 post-graduates, and 67 pupil midwives attended.

The Minister of Health, Neville Chamberlain, M.P., Minister of Health, visited Stobson-Trent on July 28th, when he opened the new convalescent block of the Bucknall Isolation Hospital, which is the first stage in the development of a large scheme of additions to that institution. Mr. Dale, the Chairman of the Joint Hospital Board, said that Mr. Chamberlain had one advantage which was not generally possessed, he believed, by heads of Government departments: he had had previous experience of the work he was now called upon to administer. He had been chairman of the Housing and Planning Committee of Birmingham City Council, and he was a member of its Health Committee until he became Lord Mayor in 1915. Since that time he had presided over the housing inquiry, which had important results. Mr. Chamberlain said that even if the Minister of Health had ten times his present staff he would still have to rely for the efficiency of the work he was called upon to administer upon the energy, vigour, and public spirit of the local authorities. What they could do at the centre was to gather together the threads from the different parts of the country.

and they could place at the disposal of the local authorities the results of the work of the best scientific men in the country; but for the real hard work for the efficient administration of the details of the actual labours which produced the results, they had to look to the local authorities and the officers who worked under them. He had always thought that one of the glories of this country was the system of local government. He sometimes wondered whether, with the complexity of local work and the growing demands upon those who were engaged on it, they would be able to go on getting men so willing to give up their time and in that respect, but he was encouraged by the appearance on every hand of new recruits in the ladies, who were anxious to be treated in their own homes; the number treated in the wards was 1,544, a decrease of 216 on the preceding year; owing to an epidemic of scarlet fever in the early part of the year the hospital was closed for a month on the advice of the local authority. All cases, whether normal or abnormal, in the district are seen by the medical officers. It does not state whether the early examinations are carried out in the homes of the patients or whether antenatal clinics are held which the patients are invited to attend. The maternal mortality for the 1,544 patients admitted was 45 (2.9 per cent.). The hospital admits serious cases from outlying districts and no one is refused if room can be made. Many of the cases are sent in by practitioners after attempts at delivery have failed. The maternal mortality was 97 (6.3 per cent.). The standard adopted for the estimation of morbidity is as follows:

The number of patients treated within the walls of the infirmary during the year 1922 was 875 more than during the previous year. Some few more beds and cots had been available during a part of the year, and with the opening of the Princess Mary ward for infants the accommodation which this provided was available for some months of the present year of the remaining large ward, which, as was mentioned in this column on August 11th, is for sick children, will probably result in a still larger number of patients being dealt with during 1923. In all 10,277 had been carried on from 1921. It is interesting to note that the number of accident cases was smaller than in 1921, which was probably due to there being less trade, but which, it may reasonably be hoped, may be the expression of greater precautions on the part of employers and greater care on the part of the workmen. The newly formed orthopaedic department dealt with 428 in-patients, and shows signs of further development. In the out-patient departments a still greater increase seems to have taken place, not so much of in-patients, but in the number of out-patients is lessened in attendances. The number of out-patients is lessened in respect of the transference of the external maternity department to the maternity hospital, and the number of new cases in the venereal department has fallen from 1,604 to 1,356. An important event during the year was the opening of the Princess Mary ward on October 22nd, 1922. The ceremony was performed by the Princess, who was accompanied by Viscount Lascelles and by the Earl and Countess of Harwood.

The financial condition of the infirmary continues to cause much anxiety to the board of management, and some reference was made to this in the chairman's speech. The deficiency on the working of the year amounted to £20,977. At the end of the year the overdraft due to the bank was, on the general account, £37,418, and on the King Edward Memorial Extension account £11,121, making in all the very serious liability of £54,539. These figures were faced with courage and with a well founded hope by the chairman. From all sources of ordinary income the amount was practically the same as in the former year, and the expenditure on many particulars lessened without any impairment of efficiency. After referring to the excellent work of the Workopole's Hospital Fund, Mr. Taylor spoke of the scheme which had been worked out by Mr. Braime, a member of the board, under which the employers of labour are to contribute a definite sum in proportion to the number of their employees. This scheme has every promise of success; it is under the immediate supervision of Colonel Bunderly, who is steadily adding to the number of employers who are associating themselves with the scheme. The claims of the infirmary were also brought before the

the smaller vessels. In the author's experience gastro-enterostomy in the treatment of chronic gastric ulcer gives unsatisfactory results in more than half the cases and compares unfavourably with resection except as regards primary mortality (1.7 to 3 per cent. as compared with 5.6 per cent.). Recurrence of the ulcer is sometimes observed after transverse resection of the stomach, but can, according to Haberer, be avoided by including the pylorus in the excision; in fifty cases treated in this way he had no deaths and the results were good. The primary mortality in resection of the stomach for carcinoma is given as about 20 per cent., and in the majority of cases recurrence, it is said, takes place within two years of the operation. Leriche records freedom from recurrence for three years in 20.8 per cent., Mayr for five years in 25 per cent., and Kocher reported cases of cure after seven, eleven, and sixteen years. The results of resection for carcinoma of the intestine show, in almost all statistics, a mortality of nearly 50 per cent. A considerable number of favourable cases have, however, been recorded. Küttner in 800 cases performed the radical operation in 32 per cent. Of these, 32.5 per cent. lived over three years, 21.6 per cent. over five years, 16.4 per cent. over eight years, and 12.8 per cent. over ten years. In forty-seven cases treated by entero-anastomosis Schloffer had a mortality of 30 per cent. and the duration of life after operation averaged three years. The mortality after excision of the rectum for carcinoma has greatly diminished in recent years, and is now between 5 and 10 per cent. Pichler reckons that the average duration of life after operation is about two and a half years, but in 440 cases operated on by Czerny and Hochenegg, 31 cases lived for over ten years. The author's statistics seem all to be drawn from German sources.

HINDLE's textbook and atlas of gastroscopy<sup>4</sup> is a handy practical volume, the subject matter of which is well ranged and the text concisely written. The atlas consists of 20 coloured plates illustrating 119 gastroscopic observations, and exhibiting the lesions in their several varieties and stages. Thus chronic ulcer is illustrated in figures showing a callous ulcer of the small curvature, the same ulcer showing the apparent alteration in size due to altered position of the gastroscope, hour-glass stomach with a chronic ulcer at the narrowed portion, cicatricial contraction of the mucous membrane, and a healed ulcer. In addition to the normal stomach the following conditions are also represented: spasm, circulatory changes, acute ulcer, the various forms of gastritis, myoma, carcinoma, sarcoma, and gastro-enterostomy. In the text the various forms of gastroscopy and their relative merits are discussed. The author speaks strongly in favour of the rigid instrument, and considers that the use of the flexible gastroscope is not free from danger. The central point of interest in gastroscopy is the degree of accessibility of the pylorus to observation; this is discussed at length, and the difficulties of the problem and the best means of overcoming them illustrated in a series of diagrams. A careful description is given of the mode of introduction of the instrument into the stomach, and the contraindications to its use. In a discussion of the difficult subject of orientation within the stomach, the principles that should guide the observer are formulated and twenty-two diagrams given to assist in mapping out the interior of the organ. In the pathological section the several diseases are treated of systematically. A general description is given of each disease, its etiology and symptoms, followed by a detailed description of the gastroscopic picture characterizing it. This is followed by notes of actual cases with the gastroscopic findings as illustrated in the plates. This section has been purposely added by the author in order to render the book of interest to a wider circle than that of the specialist in gastroscopy. At the same time the author gives a warning that gastroscopy is a difficult method and safely adopted in skilled hands only. The author expresses the opinion that if a patient of over 35 years of age is not relieved of gastric symptoms by four to six weeks of general treatment, or shows rapid wasting

which cannot be referred to any definite cause, the gastroscope should be used. In this way carcinoma may at times be diagnosed before it can be detected by other means, including x rays.

GARROD'S "INBORN ERRORS OF METABOLISM." IN 1909 Sir ARCHIBALD GARROD published his Croonian Lectures at the Royal College of Physicians of London for the previous year, under the attractive title of *Inborn Errors of Metabolism*, a phrase which has now deservedly passed into medical parlance. After an interval of fourteen years we heartily welcome a second instalment<sup>5</sup> of this work, which in a rather unusual degree combines both learning and fascination, and is what would be expected from the present Regius Professor of Medicine at Oxford. The word instalment rather than second edition is used advisedly, for not only has there been extensive revision and addition to the accounts given of the four conditions—albinism, alcaptonuria, cystinuria, and pentosuria—discussed in 1909, but two new forms—haematoporphyria congenita and congenital steatorrhoea—both of which have been fully brought to notice by his previous papers, are considered.

Of congenital steatorrhoea there are at present only three known cases, the first of which was described in 1911 by the author, who, though he gives the credit for the recognition of haematoporphyria congenita to Hans Günther, began his own well known work on haematoporphyria more than thirty years ago. With the possible exception of cystinuria the most serious inborn error of metabolism is haematoporphyria congenita, but it is very rare, only eighteen cases being recorded. This pigment greatly exaggerates the sensitiveness of the tissues to light, so that the exposed parts of the body are prone to show a disfiguring hydra vaccini-forme, the attacks recurring with the advent of summer and leading to permanent scarring and even to blindness; the bones become deeply pigmented, and the author's patient had pink teeth. The article on this subject deals exhaustively with the chemistry of the porphyrins, and, indeed, is a condensed monograph. Of pentosuria, the least conspicuous and clearly defined of the six anomalies, less is now certainly known than was supposed in 1911, for points that then seemed to be decided once and for all have now become debatable, and it is possible that several distinct errors of metabolism are included under this heading.

That there are other inborn errors of metabolism to be established is probable, and indeed reference is made to a few possible examples, such as the very rare xanthin calculi described by Alexander Marcet more than a hundred years ago. The two introductory chapters on the chemistry of the species and of the individual and on the incidence and heredity of the inborn errors, in which the application of the Mendelian principles is discussed, contain much interesting matter. The work, dedicated to Professor Gowland Hopkins, "A Friend of Many Years," represents the high-water mark of scientific medicine.

#### SURGICAL DISEASES.

THE *Pathological Physiology of Surgical Diseases*,<sup>6</sup> translated by Dr. STANLEY REIMANN from the German of Professor Rost of Heidelberg, is intended to supply the need for an exposition of surgical questions from a somewhat generalized pathological point of view, as is done, more or less routinely, in internal medicine. It makes no attempt to indicate the practical technique of surgery, but is devoted to a discussion of the principles underlying diagnosis as well as operative methods. As a guide to the proper surgical measures to be applied in a given case, it aims at presenting the physiological effects of surgery, and explain Nature's method of compensating the effects of surgical intervention. It is often difficult to obtain information on pathological-physiological questions connected with surgery, since the literature

<sup>5</sup> *Inborn Errors of Metabolism*. By Archibald E. Garrod, M.C., D.M., LL.D., F.R.S., F.R.C.P., Regius Professor of Medicine in the University of Oxford. Second edition. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton, 1923. (Cr. 8s. 6d. 7s. 6d. net.)

<sup>6</sup> *The Pathological Physiology of Surgical Diseases*. By Prof. Dr. F. Rost. Translated by S. P. Reimann, M.D., with a foreword by J. B. Deaver, M.D., LL.D., Sc.D., F.A.C.S. Philadelphia: P. Blakiston's Son and Co. 1923. (Roy. 8vo, pp. xiv+535. 6 dollars.)

<sup>4</sup> *Lehrbuch und Atlas der Gastroskopie*. Von Dr. med. Rudolf Schindler. Munich: J. F. Lehmann. 1923. (Roy. 8vo, pp. viii+132; 45 figures, 20 plates.)

and external ear are described at some length: some of these, in fact, are scarcely otological at all and fall more appropriately within the province of general surgery or dermatology. The student will, however, find the help that he is likely to require in any direction and the book can be safely recommended. The illustrations, many of which are already familiar, are excellent.

### EPIDEMIC ENCEPHALITIS.

Dr. Louis REYS's clinical study of the acute stages of epidemic encephalitis and its sequelae<sup>10</sup> is based on his observations of 150 cases of the disease during an epidemic in Strasbourg and Lower Alsace from February, 1919, to 1921. His thesis contains certain additions to knowledge: he describes a labyrinthine form which may occur in association with other signs of encephalitis or independently; he demonstrates the frequency of meningeal reactions in the disease, and gives an account of the late sequelae of epidemic encephalitis. He estimates that while about 30 per cent. of the cases recover more or less completely, 70 per cent. remain invalids for the rest of their lives. The most remarkable and frequent sequel is Parkinsonism, which is almost always progressive. As this sequel may not develop until two and a half years after the acute stages, Dr. Reys urges that every person who has had an attack of epidemic encephalitis should be kept under observation for at least three years. In discussing the prognosis of the different varieties of the disease, he states that the lethargic form is the most serious, as in 76 per cent. of the cases it ends in Parkinsonism. The myoclonic form is the next most important, as in 33 per cent. of the cases Parkinsonism results, and in 25 per cent. other persistent sequelae, such as myoclonus. The prognosis should be guarded also in the pure labyrinthine form, which terminates in Parkinsonism in one out of every three cases. On the other hand, the outlook is much more favourable in the monosymptomatic ocular form. Dr. Reys excuses the absence of a bibliography, which is usually a prominent feature in a French thesis, on the plea that the literature of epidemic encephalitis has grown to such enormous dimensions that the enumeration of even the most essential works is impossible.

The thesis is a valuable contribution to the clinical study of epidemic encephalitis, and is all the more interesting as consisting mainly of the author's original observations.

### NOTES ON BOOKS.

THE *First Aid X-ray Atlas of Fractures and Dislocations*,<sup>11</sup> by H. C. ORRIN, is what its title suggests: The numerous illustrations are its essential feature; photographs of the various bones are contrasted with radiographs of typical fractures and dislocations; in addition there are photographs of the cases after the bandages and splints used for first aid have been applied. In the text the skeleton is described, a short account is given of the reasons for the names of many of the bones, each bone and joint is considered separately, and then follow chapters on the various kinds of fractures and dislocations and their suitable treatment. Radiographs are now such a usual feature of books on medicine and surgery that they are almost taken for granted; it is of interest to note that the author of this little manual has recognized their value as illustrations for first-aid teaching; it will be remembered that he had already used radiography for a first-aid atlas of the arteries.

The second part of the second edition of *Grundriss und Atlas der Speziellen Chirurgie*<sup>12</sup> is an improvement on the first, a notice of which was published on May 12th (p. 815). It deals with the surgery of the abdomen and its contents, the uro-genital system, the pelvis, and the surgery of the extremities. More attention should have been directed to modern investigations and methods. For instance, the author in discussing the treatment of congenital hypertrophic

stenosis of the pylorus advises dilatation of the pylorus according to Loreta's method, pyloroplasty or gastro-enterostomy, but makes no mention of Rammstedt's operation of simple division of the hypertrophied musculature down to the mucous membrane. In the discussion of gastric analysis no mention is made of the fractional test meal. In addition to the ordinary anterior and posterior methods of performing gastro-enterostomy, it would seem superfluous to describe two others which are never done nowadays. Excision of the stomach is to be done on the lines evolved by Billroth. For the operation of colostomy a small piece of iodoform gauze is to be passed through the mesentery of the colon for securing the spur, and Murphy's button is commended. All the varieties of hernia are fully described and illustrated. Bassini's and Kocher's methods are advocated for the radical cure of inguinal hernia. In the operation for femoral hernia the whole thickness of the pectineus is divided and the upper part stitched to Poupart's ligament to obliterate the crural canal. The chapter on genito-urinary surgery is perhaps the best; most of the recent investigations on the renal function are mentioned. The remainder of the book deals with the extremities, fractures, dislocations, deformities, joints, and a short description of the various amputations and ligation of vessels. The treatment of fractures, according to the diagrams, seems complicated and the splints insecure.

Dr. ISABEL EMSLIE HUTTON has written a small book on *The Hygiene of Marriage*,<sup>13</sup> which gives in clear language and in sufficient detail an outline of the physiology of sex functions and much sensible advice on conjugal relationships. As Professor Louise McLroy observes in an appreciative foreword to the volume, "The medical profession realizes how much has to be learnt by the pure and clean minded before marriage can be successfully undertaken; it is obviously the most moral who are the least experienced." This book, we consider, is one which could with advantage be recommended by medical practitioners as suitable for parents to hand to sons or daughters who are about to marry. The language is quiet but explicit, the taste and tone are unexceptionable, and the information is generally in accordance with scientific knowledge. In the short chapters on birth control and methods of contraception Dr. Hutton handles a difficult subject with common sense and discretion.

The fifth edition of Dr. ELIZABETH BUNDY'S *Textbook of Anatomy and Physiology for Training Schools and other Educational Institutions*<sup>14</sup> has been revised by Professor Martha Tracy and Dr. Grace Watson, both of Philadelphia. It is not a book having any medical pretensions, but appears well adapted to the purpose for which it has been compiled.

*Green's Manual of Pathology and Morbid Anatomy* has been well known to many generations of medical students. The original edition appeared in 1871 and constituted almost the first systematic introduction to English students of the cellular pathology associated with the name of Virchow. It must be a source of gratification to Dr. Thomas Henry Green to see his literary offspring attain its jubilee and to know that it is still appreciated by successive generations of students. The present is the thirteenth edition,<sup>15</sup> revised and enlarged by Dr. W. C. BOSANQUET and Dr. G. S. WILSON. The general features of the book remain unaltered, but a considerable amount of new material has been added and many portions have been practically rewritten. The illustrations now number nearly 250 and there are several new coloured plates. The medical student is supplied in this book with a solid foundation of morbid anatomy and pathology on which to base his clinical and therapeutical practice.

The forty-first issue of the *Empire Municipal Directory and Year Book*<sup>16</sup> affords, like its predecessors, a convenient summary of much useful information not readily accessible elsewhere. The lists of municipal authorities and their chief officers throughout the Empire and the summaries of legislation, orders, regulations, and departmental circulars affecting local authorities have been brought up to date. A list of universities and colleges granting degrees and diplomas in public health, with details of the courses offered, notes of

at odd times; in a cottage hospital a whole ward may be shut up for a month for cleaning purposes and the next month another ward may be closed and then every bed may be full for a couple of months. Even under the best management, assuming that the averaging number of unoccupied beds is 27 per cent, there would last year have been only 650 cottage hospital beds that one might call avocably unoccupied—that is, barely two beds per hospital; and as they would be unoccupied at such irregular times it is doubtful whether they would in practice be available for convalescent or maternity cases which are the two important suggestions made by Sir Xapier Burnett.

Two years ago I should have agreed with him as to the use of these beds for convalescent patients from the central hospitals, but in drawing up a scheme for the co-ordination of the hospital work in this country, when we came to consider the proposal in detail, we found the suggestion as to convalescents to be impracticable unless special extra beds could be provided for the purpose.

With regard to maternity beds, I have long looked forward to the time when every cottage hospital should have a maternity ward, but I do not think it would be possible to use odd beds in general wards for this purpose. I should be sorry if Sir Xapier's report did anything to check the growth of general practitioner hospitals which are fast becoming such an important part of the medical service of the country. That they want in very many instances reorganizing and reforming there can be no doubt, but that is not a reason for doing away with them—in fact, experience has shown that an increase in the number of beds in a cottage hospital often means a higher average of occupation.

Reference in the report is made to some hospitals that undertake too much and others that do too little, but there must always be a considerable difference in the quantity and the nature of the work they do. The role of a cottage hospital is to provide for those cases that can be treated by the general practitioners of the neighbourhood and which do not require the special skill and equipment found in the central hospital; at present in many of these a large number of beds are occupied by patients who might well be treated in the surrounding general practitioner hospitals.—I am, etc.,

BRADFORD-ON-AVON, Aug. 19th.

CHARLES E. S. FLEMING.

## TRACHOMA AND VISUAL STANDARDS DURING THE WAR.

SIR,—The publication in *Guy's Hospital Reports*, by Lieut.-Colonel Eason, now Superintendent of Guy's Hospital, raises two most important questions. I have already drawn attention to these in two publications of other I. Vision of the Possible. The wealth of instance now given by Colonel Eason may induce the authorities to take definite action.

In the first place the experience of oculists in Egypt and Palestine makes it certain that trachoma is not readily contagious, and is not indeed contagious at all in the ordinary sense of the term. It is only contagious when associated with crowding and with dirty habits. The fact remains that tens of thousands of British and Australian soldiers were in close contact with a population which is almost universally infected with trachoma, and that very few contracted it. The army explanation, which may be correct, was that infection was stopped by the abolition of the pillow towel. In Australia thirty years ago trachoma was very common, and the cases came chiefly from the country districts and especially from dry, hot and sandy districts. As wealth has increased and the conditions of living improved, there has been a most noticeable decrease in the quantity of trachoma, and it would be very difficult to-day to collect a hundred cases. In other words, trachoma is not contagious except when it is associated with very insanitary conditions. An ordinary white population has nothing to fear from it. It is, therefore, obvious that the

Legislation against the admission of trachomatous patients into different parts of the world is capable of some modification so far as the risk to inhabitants is concerned. In the second place Colonel Eason shows definitely what we felt acutely in Egypt and Palestine—namely, that the visual standards established prior to the war and in the early part of the war were far too severe, and were illogical. All wars in the future will be national wars, and if men are to be excluded from service because they have a running ear or their vision is not perfect or their teeth are not good, then the nation that adopts such a standard is almost certain to be defeated. If the use of glasses is to be permitted, then it is almost immaterial what the soldier sees without glasses. The standard adopted by Colonel Eason of 6/24 with or without glasses in one eye, and absence of blindness in the other, should work quite satisfactorily considering the work the modern soldier does. Such vision is quite good enough in the majority of cases, as our experience demonstrates. It would be interesting to ascertain how many additional men could have been obtained for the British Army by the adoption of such a standard, and whether they might not have avoided the defeat of the Fifth Army in March, 1918, if they had been available. The point, however, is that both Lieut.-Colonel Eason and I from practical experience in the theatre of war have had our opinions respecting both trachoma and standards of vision completely altered. Those who have not had the same experience may be a little sceptical, and I suggest that they examine the matter from a critical standpoint. Finally, the appalling damage done by purulent ophthalmia amongst the Turkish prisoners, many of whom were suffering from pellagra, draws attention to the expert-mental work done in the production of keratomalacia in animals by a pellagrous diet. The diet of the Turkish soldier was evidently insufficient when combined with heavy military work, and notwithstanding the excellent treatment both with regard to food and medical attention, which they received after capture, it was quite impossible to save a number of them. I should think that there has never been a campaign in history from which there is so much to be learned as from the campaign in Egypt and Palestine. The theatre of war was cut off from all political influences, and was placed under one command, so that the problems to be faced were obvious to anyone interested. I advise those interested in ophthalmology to go through Colonel Eason's publication carefully.—I am, etc.,

JAMES W. BARNETT,  
Lieut.-Colonel R.A.M.C. and A.M.C.

## EXAMINATION IN OPHTHALMOLOGY.

SIR,—So one, I fancy, will be disposed to quarrel with your contention (British Medical Journal, August 4th, p. 193) that clinical ophthalmology ought to receive recognition in the final examination for medical degrees and diplomas. But surely neglect of this recognition is not so complete as you suggest. A large area of clinical ophthalmology is an essential part of general medicine and cannot therefore be excluded from the examination in medicine. Obviously this is true of disturbances of the oculomotor system, of alterations in the visual fields, and of the manifestations of alterations in the ophthalmoscope. Presumably teaching on these subjects is practised in the medical wards, and certainly questions dealing with them are open to the examiners in medicine. How then can students know that they will not be examined "on such topics? In a fairly long experience as a university examiner in medicine I have always felt free to put questions on medical ophthalmology and have long experience as a university examiner in medicine I have

It may, perhaps, be desirable to cultivate a similar development on the topical or surgical aspects of the subject, but to suggest that because there is no "special ophthalmological examination" conducted by ophthalmic surgeons "the student" cannot be expected to give much attention" to ophthalmology is a proposition that may

## Nova et Vetera.

CHARLES GABRIEL PRAVAZ.

VERY little is heard of orthopaedic practitioners before the time when Stromeyer recalled the attention of surgeons to deformities and their treatment. In this country Chessher's name has survived, thanks among others to George Eliot, but we only have allusions to him and his methods. Shaw and Harrison, especially the former, were pioneers in the treatment of deformities in the first generation of the nineteenth century. A name which arises in one's memory is that of T. Sheldrake, who was consulted by Byron after another man of the same name had failed to cure the poet. Sheldrake bulks large in the early issues of the *Lancet*. In the volume for 1828-29 there are nine communications from this gentleman, some of them of considerable length, with a commendatory note from the editor; yet from all this mass of verbiage it is impossible to gather what means he employed to achieve the cures of club-feet of which he boasted. Sheldrake asserted that he had studied under the Hunters and others, although he had no legal qualifications. Despite the sponsorship of Mr. Wakley, we must conclude that his methods were those of a quack.

A very different personage, and of a later generation than Sheldrake, was the French orthopaedist Pravaz, who is best known as the inventor of the syringe with a hollow needle which has since been known by his name. This was devised by him in order to inject iron perchloride into an aneurysm, and it was the parent of all the needles and syringes so widely used for aspiration and injection at the present day. At first the needle was made in two halves which were soldered or brazed together, but after the war of 1870 the well known surgical instrument maker Mouton bought from the French Government its stock of mitrailleuse barrels and drew them out into hypodermic needles, thus affording a striking analogy to the prophecy of Micah. Attention has recently been called to the importance of the work of Pravaz by Dr. Grangée of Aix-les-Bains in the *Revue de Thérapeutique Moderne Illustrée*. This writer gives the credit of having been the first to use subcutaneous injection of a drug to a Scottish surgeon named Wood, whom we are unable to identify.

Pravaz was born in 1791 in the south-east of France, and became Doctor of Medicine at Paris in 1824. Connected by marriage with the proprietress of a girls' school, he attended the pupils professionally and thus had his attention directed to the treatment of scoliosis, and ultimately the girls' school became an orthopaedic institute. He cannot have had a very extensive experience of curvature of the spine when, in 1827, he published his *Méthode Nouvelle pour le traitement des déviations de la Colonne vertébrale*. Nevertheless this book and his clinical work were favourably reported upon by a commission of the Academy of Medicine in 1829. In it he described his progressive extension bed, which figured later in his treatment of congenital dislocation of the hip; he paid tribute to the work of Bampfield, Shaw, and other surgeons of this country, whose foggy sky and damp climate favour (so he says) the production of deformities.

But Pravaz's chief claim to remembrance as an orthopaedic surgeon is the advance he made in the treatment of congenital dislocation of the hip. According to Malgaigne, Humbert de Morley had published in 1835 an account of five cases of this deformity of which the cure was said to be confirmed, but these successes were generally regarded as equivocal. Pravaz then took up the question, and after a much-talked-of successful case which afterwards relapsed, he presented to the Academy of Medicine in 1838 a girl whose cure was vouched for by a commission. The Academy sanctioned the conclusions of the commission, although Dr. Bouvier strongly dissented. Pravaz, who had removed his orthopaedic institute to Lyons, persevered with his method, and in 1847 he published his *Traité théorique et pratique des luxations congénitales du fémur*, in which he gave details of nineteen cases. Between the date of publication

of this monograph and his death he treated eight more cases, making twenty-seven in all, with a percentage of success at least as high as that attained nowadays, if we are to credit the testimony of the numerous surgeons who examined a number of his patients some years after their cure.

Pravaz alone in his time seems to have seized upon some at least of the principles by which congenital dislocation of the hip can be cured. He relied on long-continued extension with weights amounting in some cases to more than 40 lb., after which he reduced the dislocation by abduction and pressure on the great trochanter and maintained the reduction in the abducted position by means of a belt. He seems to have realized thoroughly the necessity of re-forming the articulation of active movements of the thigh and consequent pressure and friction of the femoral head in the acetabulum. All these measures, except the first, are now recognized as right and necessary. Pravaz had not the advantage of using plaster-of-Paris, which was then only beginning to be employed by Bouvier in Paris for the treatment of club-foot, and his apparatus appears to have been elaborate and difficult to manage. There can be no doubt of the functional value of his results in many cases, and if, as Professor Nové-Josserand of Lyons has recently suggested (*Revue d'Orthopédie*, May, 1921), his cures were not genuine reductions, but anterior transpositions, his patients were nevertheless immensely benefited thereby.

When Pravaz died his success was still disputed in Paris and elsewhere. Malgaigne in his classical work on fractures and dislocations stated that he had not seen any of the cured cases. Gillebert D'Hercourt, the pupil and successor of Pravaz, continued his practice at Lyons and published a number of pamphlets vindicating the method and its author, but gradually both fell into neglect and oblivion. This neglect is hard to explain. Possibly if the orthopaedic institute had been in or near Paris it would have won greater appreciation and the profession of the capital would have had better opportunities of testing the worth of Bouvier's dicta, that congenital dislocation of the hip was incurable and that no case had been cured. Bouvier was at that time a great authority on orthopaedic surgery and his influence, coupled with the complexity and long duration of Pravaz's treatment, probably retarded progress for forty years, that is until Pacci rediscovered the principles of Pravaz, and Lorenz added to them and improved their application by using plaster-of-Paris. Whatever the cause, it is a tragedy that nearly two generations of hip-luxated cripples should have been deprived of benefits such as they might have enjoyed had the work of Pravaz been carried on.

## MINERS' NYSTAGMUS.

THE Miners' Nystagmus Committee appointed in 1920 by the Medical Research Council was invited by the Home Office, and later by the Secretary for Mines, to give special attention to the great increase which was taking place in the claims for compensation due to miners' nystagmus. The Committee issued a first report about fifteen months ago; it dealt generally with the subject of miners' nystagmus as an occupational disease. Its main conclusions, which were given at some length in our columns of April 22nd, 1922, were that the essential factor in the production of miners' nystagmus is deficient illumination, due to the low illuminating power of the safety lamps generally used; that workers at the coal face are more affected than other underground workers; and that distinct signs of nystagmus are present in a large proportion of coal miners, though only in a small proportion do the symptoms ever become so severe as to cause even temporary incapacity for underground work. The Committee recommended that the standard of illumination should be improved by the use of the electric cap lamp, or some other method which brings the light near the working area without shining directly into the eyes, and by an increase of whitewashing and stone-dusting.

With regard to Dr. Kidd's surmise that the whole epidemic of diagnosis of Rickets and Wanklyn were not violated. On the palms and soles, and yet to show that the principles of diagnosis of Rickets and Wanklyn were not violated. I may say, perhaps, that one of the Birmingham cases was an unfractured child who had a history, and who showed typical scars, of a previous attack of chicken-pox. The total number of small-pox lesions this child presented was certainly not more than thirty. The distribution of these lesions and the character of the lesions themselves were typical of small-pox. The child was in a hospital—unconscious—[am, etc.]

Aug. 6th.  
 Medical Superintendent, City Hospital, Little Bromfield.  
 E. H. R. HARRIS, M.D., Lond.  
 of Birmingham.

1. Do cases of confluent small-pox occur, and are they liable to occur in most epidemics of the disease or not?
2. Does the disease ever cause disfigurement by pitting and opacities of the cornea or not?
3. Do the returns show that vaccination, and only vaccination, is the safeguard against attacks of small-pox or not?

These are well known facts and could not be called exaggerations; it is upon these facts that I have based my suggestions.

an exposition of the doubt that exists (according to Dr. C. Killick Millard) as to the protective power of vaccination against small-pox. Personally, in spite of Dr. Killick Millard, I am still

quite convinced that my suggestions are fair and expedient, and if carried out would go a long way towards convincing the layman of the advisability of being vaccinated against small-pox.—I am, &c.

L.R.C.P. and S.Ed., D.T.M. and H.Lond.  
Buddleigh Salterton, Aug. 6th.

CANCER RESEARCH.

Sir,—Dr. Leonard Molloy's letter in your issue of August 11th requires correction in one or two essentials. The British Empire Campaign is distinct from the

Imperial Cancer Research Fund, the latter has been in existence for twenty years. The British Empire Cancer Campaign is not yet in existence as an organization. Dr. Molloy says that the Treasury grant to the Imperial Cancer Research Fund is "utterly inadequate." This is an erroneous statement. In this case, because the Imperial Cancer Research Fund is not now and never has been in receipt of Government financial

cial support, although several Government departments are represented on its General Committee and Subcommittees.

Permit me to add that I disagree with the implication in Dr. Molloy's letter that the only requirement for success in cancer research is money. It is a libel on men of science in this country to suggest that the trained intellects capable of solving the pathological and therapeutic problems of cancer are here and only waiting for the money to tempt them to engage in these problems.—I am, etc.,  
J. A. Murray,  
Imperial Cancer Research Fund,  
8-11, Grosvenor Square, W. 1.  
Aug. 1936.

the first time I had ever been in a car, and I was very nervous. I was sitting in the back seat, and I was looking out the window. I was seeing a lot of things that I had never seen before. I was seeing a lot of people who were different from me. I was seeing a lot of things that I had never seen before. I was seeing a lot of people who were different from me. I was seeing a lot of things that I had never seen before. I was seeing a lot of people who were different from me.

obtained.—I am, etc.,  
O. CLAYTON-JONES, M.B.Oxon.  
Silverton, nr Exeter, Aug 6th.

Mr. Charles Symonds certainly gives some useful information, but I do not think anyone would care to assert that the letter makes the position look any brighter or more encouraging.

To my mind it appears particularly unfortunate that so important a functionary as the treasurer of the fund should feel constrained to take refuge in the very much overwrought excuse of "apathy of the profession."

I am no believer in this explanation. The average medical man who is called by the law to work to the point of near-concussion is not in a position to do any more than to say that he is not a doctor, and this process of being called in to advise on important matters during every day of his existence is a process of being called in to advise on important matters during every day of his existence.

appear to be minor considerations. In my opinion, therefore, the fault lies in his never having brought to realize that he has a definite moral obligation towards the

poor and distressed of his profession. If I am correct in this assumption, the remedy must lie

## British Medical Journal.

SATURDAY, AUGUST 18TH, 1923.

### THE REMUNERATION OF INSURANCE PRACTITIONERS.

THE Minister of Health has undertaken to inform the medical profession, by October 1st next, what his proposals are for the terms and conditions of service of insurance practitioners for the year 1924 onwards. These terms and conditions are a matter not only of professional but of national importance. The national object is to secure for certain large classes of the population medical attendance and treatment of the type contemplated in the insurance scheme, upon conditions such as will obtain for the insured person a wide freedom of choice among practitioners, and service from any practitioner chosen certainly not inferior to that which could be given under any other system. To secure this from the profession it is essential that the extent and character of the services required shall be clearly understood, that the conditions under which these services are to be given are not inconsistent with the honourable traditions of the profession as interpreted by its representative authorities, and that the financial reward of the services shall be such as to justify the expectation that every practitioner will use his highest skill and utmost endeavour in the interest both of his individual patients and of the national health. These three essentials cannot be separated; without any one of them there will be relative failure. Attention must not be concentrated upon the question of money payments to the exclusion of the others, nor should this be regarded as of more or less importance than they.

For many months past the Insurance Acts Committee, on behalf of insurance practitioners and with the authority of the British Medical Association, has been engaged in an investigation with regard to the first two of these points. It has sought information from the Ministry, from Insurance Committees, from approved societies, from all and sundry, as to all those things in which it was alleged, rightly or wrongly, that the insurance service was imperfect or that the work and conduct of practitioners was less satisfactory than it should be. It is acknowledged that, here and there, there are some practitioners who are doing less than may properly be required of them; and that there are a number of imperfections in the service as a whole, though it is found that these are due by no means always to the doctors but mainly to the ignorance or carelessness of insured persons themselves or to difficulty or laxity of administration in other quarters. The Committee has made, or has accepted, a number of suggestions which, it is believed, meet all legitimate criticisms, and which must, if carried out, be to the great advantage of insured persons and of the service generally. They are contained, in the main, in a memorandum published in the SUPPLEMENT to the JOURNAL of May 19th last, though they were amended in some minor details by the Conference of Local Medical and Panel Committees in June and July.

They have, moreover, been regarded as such by a number of the most influential and representative members of Insurance Committees and of Societies.

There is only one important point on which misunderstanding still appears to exist in some quarters. It is understood that the range and extent of attendance and treatment to which insured persons are entitled under the scheme is that which is properly given by general practitioners as well as that services of a specialist character, whomsoever given, have to be provided for in the same way. Any restatement of this is not designed to emphasize the width of this service, and to ensure that, while not impugning the right of any registered medical practitioner to any medical or surgical service which he deems appropriate, no insured person shall be charged for any treatment unless it is proved to be of a special type, and unless any insurance practitioner himself gives it is judged to have the special character or skill desirable. It may be that it is financially necessary to maintain at present this limitation on the range of service; or it may be that the insurance arrangements are so ample that they could bear the cost of a complete specialist and institutional as well as a complete general practitioner service. Some of the approved societies appear to believe that it is not improbable that the whole expenditure on health services might, if more widely distributed, be capable of meeting the cost of unlimited service; and it is certain that the profession is not only willing but anxious that the service shall be made as complete as possible under appropriate conditions. The immediate point to note, however, is that in discussing the remuneration of insurance practitioners reference is made now, as it has been, to a service of the general practitioner type, wide, highly skilled, comprehensive as that service must be recognized as being.

More recently the attention of the Insurance Committee has been specifically directed to a calculation of the capitation fee on the basis of which will be formed the Central Practitioners' Fund, on the proportionate distribution of which each practitioner's remuneration depends. The Committee's very important memorandum on this subject was published in the SUPPLEMENT to our last week's issue. The starting-point for such calculation is the arbitrary award of 11s. early in 1920. This has to be adjusted to the conditions of the immediate future. The adjustments required are for the cost of living and of carrying on practice. An authoritative statement as to the former of these adjustments will be found in the memorandum by Professor Bowley, published in connexion with that of the Committee. On the basis of the finding of an independent scientific economist the Committee is entitled to rely. The arbitrator gave no reasons for their award, but it is permissible to search for some definite calculation that may be presumed. There is one such calculation which the Committee has not explicitly set out in its memorandum but which entirely supports the figures at which it had arrived. The average original capitation fee was 7s. 3d., but the minimum available in some areas was only 7s. The percentage increase claimed (on the grounds now under consideration) in 1920 was 60, and though Professor Bowley agreed that this

ROBERT ANDERSON, M.D. Edin.,  
Gateshead.

On August 6th, with tragic suddenness, Dr. Robert Anderson of Gateshead passed away. Although in his 80th year Dr. Anderson was well preserved, and was busily occupied until the day of his death. It was the present writer's privilege to have known Dr. Anderson for over forty years, during which nothing ever occurred to mar the friendship. At the early part of the period referred to, Dr. Anderson was a busy colliery doctor at Seaton Delaval, a few miles from Newcastle-upon-Tyne. The death of Dr. Davidson, to whom he had acted as assistant, threw large practice, he became surgeon to several of the collieries and had sometimes to employ five or six assistants. Dr. Anderson carefully supervised their work, visited the collieries daily and was always at the call of his assistants. He thus knew his patients and their families intimately, and entered into the joys and sorrows of their family life, and was looked upon as a friend as well as their medical adviser. Notwithstanding his many duties, Dr. Anderson found time to deliver evening lectures in neighbouring villages on health and social problems, and thus helped to stimulate among the Northumbrian miners that desire for learning which has been so characteristic of them as a class. Dr. Anderson was in the North of England and the first medical man to introduce an organized ambulance service into the collieries. He became one of the most active and inspiring members of the St. John Ambulance Association, and for years he drilled and instructed the miners so that they might be able to deal in the gentlest and safest manner possible with their comrades injured underground. Many honours were bestowed by the central authority of the Order of St. John of Jerusalem upon the late Dr. Anderson in recognition of his important services. Only a few months ago he retired from his position as Assistant Commissioner of the No. 6 District of the St. John Ambulance Brigade. Twenty years ago he retired from the greater part of his active medical duties and came to Gateshead, but only to identify himself with public work, and of honorable dealing with his patients and the medical profession. He was a fluent speaker and upon subjects with which he was well acquainted he frequently, years ago, endured debates at the meetings of the Northumbrian and Durham Medical Society. There was a freshness in his views which appealed, knowledge based upon experience which convinced, but above all an openness of mind which made him receptive to new ideas and methods of treatment. He was dedicated—as it was his pride to recount—at Edinburgh University during the painful days when among its medical professors were numbered such men as Syme, Simpson, Hughes Bennett, and Christison. He graduated M.D. Edin. in 1864, and took the diploma of L.R.C.S. Edin. in the same year.

A member of the Established Church of Scotland, Dr. Anderson was for fifty years an elder in the Presbyterian body. During the last twenty years he acted in this capacity in Park Terrace Church, Gateshead, and there, prior to the interment in Saltwell Cemetery, a service was held, attended by the Mayor and Corporation of Gateshead, representatives of the medical profession and of the St. John Ambulance Association, and by a large body of the public, by whom he was held in high esteem. He is survived by his widow, two daughters and three sons.

T. O.

Dr. Oliver Smith passed away peacefully in his home in Gorseon on August 5th. Though he was only 41 years old, he had already made his mark, and was greatly respected by his fellow practitioners as well as by his many patients. After a distinguished career at Edinburgh University he spent several months at sea as a ship surgeon, and then held the appointment of house-surgeon at the Great Western Hospital. Here his conscientiousness and professional skill were greatly appreciated, and when his term of office came to an end he was invited by Dr. P. G. Gilmore to join him in a partnership, which lasted fifteen years till Dr. Oliver Smith passed away peacefully in his home in Gorseon on August 5th.

Smith's death. It was a matter of regretful wonder to his closest friends that he did not engage in research work, for which his keen intellect seemed to fit him. Though his practice was growing steadily, he managed to read much and keep abreast of the times, and his scientific bent showed itself in his love of instruments of precision. He showed infinite pains, and never committed himself to a diagnosis or line of treatment till he had carefully weighed all the available evidence. It follows that he had seldom to perform major operations till his illness at last forced him to give up work. He was confined to bed for about six months. He bore his crushing reverse of fortune with infinite courage—a courage which his wife also showed to a marvellous degree. She nursed him day and night throughout his illness, showing a sublime fortitude and disregard of self. It is no exaggeration to say that all Gorseon was plunged into grief by his death, and his former patients realized that they would no longer be cheered by that kindly smile which used to light up his clear-cut, intellectual features. He was a member of the East Norfolk Division of the British Medical Association.

We regret to record the sudden death, on July 22th, of Dr. Walter William Chavasseaux of Hawdon, near Leeds, at the age of 62. Dr. Chavasseaux graduated M.B., C.M., at Edinburgh University in 1887, and was afterwards house-surgeon at Birmingham General Hospital and senior house-surgeon at Halifax Infirmary. He acted as Hawdon general practice there. He was medical officer of health to the Hawdon Urban District Council, and was honorary medical officer to the Mitchell Memorial Home, Hawdon. A few months ago he was decorated by the King of the Belgians for his services to the Belgian and allied troops who were under his care at various institutions at Hawdon during the war. Dr. Chavasseaux held a high position in the estimation and affection of the residents of the district. He leaves a widow, two sons and a daughter, Sir Berkeley Moyman, in the course of an apprenticeship in the *Indian Civil Service*, writes: "Dr. Chavasseaux was one of the best types of general practitioner, and was greatly beloved and trusted by all his patients and by a multitude of friends. He knew his professional subjects well, and he devoted himself with great care and the most painstaking and untiring attention to all the details of his cases; to the happiness of his patients no less than to their material welfare. His judgment rarely erred, and a long experience had given him the power to foresee the possible developments of an illness, and the knowledge to check or avoid its consequences. . . . He was among the most popular of men; always cheerful, considerate for the words and act of others, willing to undertake another man's difficulties or to listen to his opinions."

Dr. Edward Hargreaves of Sheffield, who died on August 9th, was born at Colne, Lancs., in 1846. After serving for a few years in a cotton mill he went to study medicine at Glasgow University, where he graduated M.B., C.M., in 1874 and proceeded M.D. in 1885. He became assistant, and subsequently partner, with Dr. G. Storrord Taylor, and continued the practice after Dr. Taylor's retirement. He was a member of the Sheffield Medical-Chirurgical Society, of which he subsequently became vice-president, and was honorary surgeon to the Prevention of Cruelty to Children Society. In 1895 he was elected a member and Rescued Society. He had sat on the Sheffield magistracy since March, 1906. Dr. Hargreaves was a member of the Sheffield Division of the British Medical Association. He is survived by three daughters and one son, Dr. Robert Hargreaves, who practises at Sheffield.

We regret to record the death on July 13th of Dr. John Sinclair Holden of Sudbury, Suffolk, at the age of 56, Dr. Holden was educated at Queen's College, Belfast, and

gastric carcinoma was definitely made, stagnation was shown to exist either by the presence of visible charcoal, or the foul odour, or the high concentration of lactic acid. Dr. Ryle drew attention to the valuable information to be derived from an examination of the resting secretion of the stomach. Its amount, consistency, naked-eye appearance, odour, and cytology all supply information of great assistance to the understanding of gastric disorders.

In a discussion such as this, in which physicians, surgeons, and pathologists all took part, it was natural that there should be a certain amount of difference of opinion as to the value of different tests, their interpretation and significance; and evidence of dissension on minor points is provided by a perusal of the printed papers. But two observations were frequently made by different speakers, and seemed to meet with general approval. The lack of intimate co-operation between the laboratory worker and the clinician was deprecated, and more than once the view was expressed that if the physician or surgeon himself performed the gastric analysis he would derive far more information from the result of the test than by merely sending the specimens to a laboratory without any history or account of the symptoms. Should the clinician himself not be able to carry out the test he should give the fullest possible information to the co-operating pathologist, and not regard him as a mechanical oracle, always capable of supplying a satisfactory answer. "Yes" or "No" pathology is of little use in gastric analysis. The lack of consideration for macroscopic characters of gastric samples was frequently deplored. The advances of biochemistry have tended to direct too much attention to the difficult and complicated tests, almost as though it were to be expected that the more intricate analysis would necessarily lead to the more valuable conclusions. In this pursuit of the refinements of chemistry the naked-eye and nose evidences of the specimen to be examined are often neglected. We seem to have forgotten the valuable deductions that were made by our predecessors from the quantity, colour, consistence, and odour of the stomach secretions, and these should always be the first properties to be thoughtfully considered.

### CLEAN MILK.

EDUCATION, alike of the milk producer, the milk distributor, and the milk consumer, proceeds apace, each of the three reacting on the others. Three pamphlets just issued almost simultaneously\* are of much interest in this connexion. In one of them Dr. J. M. Hamill of the Ministry of Health gives a concise and instructive account of the whole subject of pasteurization. That process is, we presume, admitted by everyone to be merely a short cut to the production of milk which will be safe, and will keep sweet long enough to allow it to be used domestically after distribution from producer to wholesaler, to retailer, and finally to consumer. To the idealist that may seem a lowly aim, but the babies and children of this generation cannot wait through the long years that will elapse before all milch cows are free from tubercle and all dairy premises and processes

are brought to perfection. This has been realized on the other side of the Atlantic, where Chicago has made pasteurization of its whole milk supply compulsory.

In this country pasteurization is being more and more resorted to, and the Ministry of Health has done well to issue Dr. Hamill's notes on the subject. After stating exactly what he means by pasteurization, he discusses its effect on bacteria and on the chemical and physical character of the milk. He points out that pasteurized milk requires as much care in subsequent handling as clean raw milk, but at the same time he rebuts the assertion that bacteria grow faster in pasteurized than in raw milk, the rate of growth being about the same in both. Yet pasteurization will not be a substitute for cleanliness. It will reduce the number of bacteria, but the number remaining will not be so low as if the milk had been cleaner to begin with. He discusses the three methods of commercial pasteurization—"Flash Pasteurizers," "Retarders," and "Holder Pasteurizers"—and favours the last named, especially against the first. Throughout his notes Dr. Hamill confines the term "pasteurization" to the process of heating to not less than 145°F. and not more than 150°F. for a period of thirty minutes. So defined it has little or no influence on the flavour of the milk, nor does it practically affect two of the three vitamins—fat-soluble A and water-soluble B—but it does weaken the vitamin C, the antiscorbutic, and towards limitation of this effect air should, as far as practicable, be excluded during the process. Lactic acid bacteria are largely reduced and souring of milk correspondingly prevented. That the rising of the cream to the surface is partly prevented if the pasteurizing temperature is 148° or 150° is of no real consequence, as the amount of fat in the milk is not diminished, though the purchaser's suspicions may be aroused as to the honesty of the seller. The essay is full of useful information and comment, and concludes with some observations on pasteurization of milk in bottles.

In the second pamphlet Mr. A. T. R. Mattick of the National Institute for Research in Dairying at Reading discourses on the whole subject of the production of clean milk; and in the third the National Clean Milk Society describes the method of conducting milk competitions, which are now annual events in several counties. Mr. Mattick deals clearly, tersely, and with obviously intimate knowledge, with every detail of the business as it ought to be conducted. Milking sheds, cowsheds, milk rooms, sterilizing rooms, dairy utensils, churns, the conversion of coppers into steam sterilizers, the milking process, refrigerators, strainers, and bottling, are all considered. He emphasizes the importance of light and water and steam as fundamentals, but urges that these and the most modern appliances will not in themselves bring success in producing clean milk. The human element comes first. He tells all about what constitutes a first-rate cowshed, but gives a photograph of a wooden-walled, thatch-roofed, old shed, in which first-class results were obtained by a cowkeeper who had mastered the fundamental principles of cleanliness. A proper water supply, being of essential importance in respect alike of the condition of the premises, the supply of steam, the cooling of milk, and the toilet both of the cow and the milker, must lay a heavy burden on the occupier of an old-fashioned farmstead, where the water has to be pumped from a shallow well, and no doubt one effect of the new requirements of proper milk production

THE NATIONAL ASSOCIATION for the REFORMATION of JUVENILE MORALITY and for the WELFARE of INFANCY (117, Piccadilly, W.1) has arranged a course of lectures on infant care for health visitors, nurses, midwives, school teachers, voluntary infant welfare workers, and committees of nursing associations, to be held in the Lecture Theatre, University College, Nottingham, from September 24th to 28th, 1952, inclusive.

In the paragraph published in our issue of August 14th (p. 213) regarding post-graduate courses in Vienna and stating that full participants can be obtained on application to the Secretary of the Austrian Embassy, the address was incorrectly given. It should have been 18, Heugerville Square, London, S.W.1. We understand that the office is open to visitors from 11 a.m. till 1 p.m.

PROFESSOR ROBERT WIDENSHENK, the well known comparative anatomist, for many years director of the Anatomical Institute of Freiburg University, has died at the age of 75.

**LETTERS, NOTES, AND ANSWERS.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication. As, owing to printing difficulties, the Journal must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthily written documents on Monday. Authors desiring reprints of their articles published in the Journal should send them to the printer, Messrs. W. & A. G. and Sons, 1, Abchurch Lane, London, E.C. 4.

[illegible]

LETTERS, NOTES, ETC.

This condition was unchanged, except that my new treatment was weaker and thinner. Before attempting any new treatment a bacteriological examination was made. The report was negative for amoebae and dysenteric bacilli, but positive for *Entamoeba histolytica*. No specific treatment is known for that condition, so it could be found in the literature available at that time was used for its use in lamblia infections was found in one textbook, and it is the recognized treatment for hookworm. Nonetheless seemed to accure. Of equally little use were betanaphthol and creosote, the latter given in caps of 5 mm each. All the time he was given a mixture of bismuth and magnesia, with an occasional addition of incense of opium, when the pain was very bad, to soothe the irritation and griping. Starc enemies with an occasional addition of opium were also sometimes tried. Sodium sulphate treatment was also unavailing.

## THE CAMBRIDGE CHAIR OF ANIMAL PATHOLOGY.

EARLY this year, as announced in these columns, the Senate of Cambridge University accepted an offer made by the Ministry of Agriculture and Fisheries of a capital sum of £30,000 to found a Chair of Animal Pathology. The Senate subsequently approved regulations for the professorship, fixing the stipend at £1,200 per annum, and defining the duties of the chair as the advancement of the knowledge of the diseases of animals by teaching and research. Mr. J. Basil Buxton, F.R.C.V.S., who holds the diploma of veterinary hygiene of the University of Liverpool, has now been elected to the chair. He is at present attached to the staff of the National Institute of Medical Research at Hampstead under the Medical Research Council, and has lately taken part in an investigation into the efficacy of the various tuberculin tests in cattle. Together with Professor T. B. Wood, F.R.S., Drapers Professor of Agriculture at Cambridge, he is a member of the Tuberculin Subcommittee of the Medical Research Council. On taking up his duties at Cambridge Professor Buxton will have his headquarters in an extension of the School of Agriculture adjoining the new biochemical laboratory which is being built and presented to the university for Professor Hopkins by Sir William Dunn's trustees. His first task will be to prepare plans for his headquarters laboratory at the School of Agriculture; for a branch laboratory, paddocks, animal houses, etc., at the field laboratories; and for staff and equipment. Although the regulations mention teaching among his duties, it is expected that at the beginning his whole time will be devoted to organization and research. The establishment of a Chair of Animal Pathology in the University of Cambridge, in direct contact with the School of Agriculture and with the hearty co-operation of the School of Medicine, is a departure of the greatest importance which will be watched with close interest by the medical profession.

## ARC-LIGHT BATHS FOR TUBERCULOSIS.

DR. J. G. MOYLES, chairman of the Hospitals Committee of the Liverpool City Council, and Dr. C. Rundle, medical superintendent of the Fazakerley Sanatorium, have issued an interesting report on a recent visit to Copenhagen and Stockholm, to study the treatment of tuberculosis with arc-light or artificial sunlight baths. It is claimed for heliotherapy as carried out at Leysin, Switzerland, and for artificial sunlight produced by specially constructed carbon arc lights, that it produces a rapid improvement in the general health and nutrition, disappearance of pain and fever and return of appetite, repair of bone tissue and healing of sinuses and ulcers, a reduction in the size of tuberculous glands and in many cases their ultimate cure. There is no doubt that many such recoveries have taken place where the requisite amount of sunlight is obtainable. In those countries, as in the British Isles, where such conditions do not exist, carbon arc lights are employed, and in Copenhagen and in Stockholm such artificial sunlight has been extensively used in the treatment of all forms of tuberculosis. It would appear that the curative properties are present in the ultra-violet rays, and that the heat rays should be excluded. The carbon arc light is that generally used, and at a distance of one metre. Where the disease is not localized the back, chest, and flank are exposed, at first for thirty minutes; the period is then increased to a maximum of two and a half hours, and the treatment applied daily. In lupus and tuberculosis of the skin no dressings are worn during the exposure to the artificial light bath. The eyes of the patients are protected with large black spectacles. At Stockholm the effects of artificial sunlight were studied in cases of surgical tuberculosis.

Dr. Henning Waldenström, the orthopaedic surgeon, expressed the opinion that surgical measures must continue to be our chief weapon, and that artificial sunlight occupied a position equivalent only to that of fresh air, good food, and tonics, and should be regarded as an important adjunct to treatment. In discussing the treatment of tuberculous disease of the bones, the writers of the report draw attention to the fact that in the use of natural sunlight, as well as in that of artificial sunlight, complete immobilization of the affected parts is regarded as unnecessary. Cases of caries of the spine are kept only in the recumbent position when pain is present. They arrive at the following conclusions: (1) No injurious effects can result from a proper application of this treatment. (2) The immediate effect is one of exhilaration and a general feeling of well-being. (3) In certain surgical conditions the arc lamp effects a cure in conjunction with surgical measures more rapidly than when the latter alone are used. (4) The treatment is of value in tuberculosis of the larynx, so intractable often to other remedial measures. They are unable to assert that the arc lamp possesses a definite curative value in lung disease beyond those measures already known. In view of its beneficial action in certain types of tuberculosis the authors recommend the installation of one arc-light unit at the Fazakerley Sanatorium.

## A NURSERY TRAINING SCHOOL.

DR. ERIC PRITCHARD contributes to *Country Life* of August 11th an interesting note on the Nursery Training School, Wellgarth Road, Hampstead Garden Suburb, to which he is honorary consulting physician. This institution was established twelve years ago in an East End slum; it moved to its present sylvan quarters in 1915. It was originally founded through the efforts of the Women's Industrial Council, the object being to open up a useful career to women. The girls who come to it as students on probation are drawn from all classes of society; most of them have received a good secondary education and some are the daughters of professional men. Great care is taken in choosing the students, for it is recognized how much little children depend for their own character and manners on the example and precept of those who look after them. As a rule, the girls or their parents pay the fees themselves in advance; but occasionally the fee is paid out of State grants or in the form of a scholarship. The period of training is one year, during which a student serves an apprenticeship in the nurseries, laundry, kindergarden, kitchen, and needle-room. She also attends lectures on mothercraft, elementary hygiene and physiology, and domestic economy, and she has opportunities of visiting the welfare centre in Marylebone. The aim of the committee and staff is to make the training as little like that of a hospital and as much like that of a well conducted nursery as possible. The buildings were designed to combine the maximum of open air and sunshine and isolation at a minimum of cost; the illustrations to Dr. Pritchard's article show how charmingly the architects have carried out the ideas of the committee. Two long open galleries, facing south, one above the other, run from end to end of the building. These galleries communicate with the outside, and with the nurseries and other rooms within, by means of hinged folding windows. Except in very cold weather, or when the children are being bathed or dressed, these folding panels remain open; each nursery is thus practically open on one side and looks out on to the garden and the fields beyond. The housework is done by the nurses themselves. Between twenty and thirty girls pass out of the school each year, ready to take charge of the children and nurseries of middle-class families.

EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

**Lupus Erythematosus.**

F. GARNIER, (*Eduard's Med. Journ.*, June, 1923, p. 233) considers that lupus erythematosus is on the increase, and from an experience of thirty-four cases (one with *post-northern* report) tuberculosis, streptococcal infection, rheumatism, and exposure to bright light or heat were among the causative factors. There is no local damage in treatment, the patients play up past history, as in other skin afflictions, having no common predisposing diathesis, the lesion being due well as to the hands and face, and such cases may improve after treatment with horse serum, and markedly resistant to all other remedies. In treatment all possibilities of relapse must be removed, and a vaccine therapy may be used in conjunction with the application of either mercury or iodine locally, sootings, confinement, as well as the whole, while alive to present developments, does not forget past remedies.

## BACTERIOLOGY OF CONDENSED MILK.

THE Food Investigation Board has issued a report by Dr. W. G. Savage and Mr. R. F. Hunwicke on condensed milk.<sup>1</sup> It consists of two parts, the first being on sweetened condensed milk and the second on unsweetened, each part representing the results of a separate inquiry.

In an introductory note the Chairman of the Board, Mr. W. B. Hardy, F.R.S., points out that one of the difficulties attaching to the high nutritive qualities of milk is that bacteria and yeasts are able to grow freely in it. As an industrial product, therefore, the utmost circumspection and skill are called for on the part of those who handle it, whether their task be its distribution in the fresh state or the preparation of the canned form. The difficulty of the manufacturer lies in the fact, not peculiar to milk but common to all decomposable foodstuffs, that the process of sterilization if pushed to finality alters the product and may impair its more subtle nutritive properties. He has, therefore, to control the milk from the first so as to keep the bacterial content as low as possible, and to confine his methods of sterilization within certain narrow limits imposed by the chemical instability of milk itself and by the necessity for the destruction of practically all the micro-organisms present. The report naturally concentrates attention upon failures and the causes of failure. Nevertheless, though condensed milk as marketed is rarely sterile in the strict bacteriological sense, the methods of manufacture in up-to-date factories are such as to reduce the number of intrusive organisms to harmless limits.

## I. SWEETENED CONDENSED MILK.

Two main varieties of sweetened condensed milk are produced commercially, the full cream and the machine skimmed—differing in the fact that the former consists of concentrated whole milk, whereas in the latter practically all the fat has been removed. The trade in full cream sweetened condensed milk is large and increasing; hundreds of tons are imported annually and there are also many factories in this country.

*Methods of Manufacture.*

The following are the essential details of the usual methods of manufacture:

Factories are situated near milk producing districts, and the milk, when received, is weighed or measured and either passed into a large tank in which it is heated, or through a flash pasteurizer. The maximum temperature reached is ordinarily between 80° and 90° C., at which it is retained for a few moments. Bacteriologically the point of importance is that the temperature is insufficient to kill many types of bacteria and cannot be relied on for this purpose. After heating the milk, sugar is added, either by mixing direct with milk or by running in concentrated solution which has been boiled. The sweetened liquid now passes into vacuum pans from which the air has been partially exhausted so that the milk boils at a low temperature, about 50° to 60° C. The time taken to evaporate each batch of milk to a suitable consistency is about three hours, the condition being estimated from samples withdrawn periodically and examined for viscosity, or by the hydrometer. The evaporated milk is emptied into cooling vessels and then transferred to tins by machines which deliver a fixed quantity to each tin. The tops are placed on by hand and fixed in position by a machine. The tins of condensed milk are not stored but placed on the market at once.

Though the milk is obtained from the vicinity, and therefore fresh, it is not necessarily clean and commonly contains large numbers of bacteria and a good deal of dirt. Most non-sporing bacteria are killed by the preliminary heating, but the milk may easily be infected from the pipes conveying the condensed milk to the tins, and the ordinary method of cleaning these with live steam is inadequate. Bacterial infection is often attributed by the manufacturers to the sugar, but if stored dry it probably does not introduce many organisms when added to the milk. The air of the factory, disturbed by the constant traffic of the workers, has been shown to be heavily charged with yeasts and large numbers of bacteria and the method of cooling the milk in vessels with open tops invites aerial contamination. Com-

monly these cooling rooms, instead of being set apart, are found in the middle of a factory, in the line of ordinary traffic. The cooling vessels ought to be placed well above the ground and the floor kept thoroughly wet; overall, should be worn by those who work in the room. The tin receptacles for the milk are not usually sterilized before being filled, and if not made on the premises may be dusty.

*Methods of Inspection.*

On arrival from abroad tins of condensed milk are inspected for bulging, leaking, excessive rust, or mishandling of tins; the majority of tins rejected are so dealt with because definitely "blown." Suspicion attaches also to a springy condition or evidence of pressure detected by the feel of the can. The judgement of the food inspectors was confirmed by laboratory tests in 87 per cent. of the tins. The difficulty of correct judgement arises chiefly in connexion with tins which are "springy" but which do not show any sign of gas; some are unfit but more are sound.

*Bacteriology of Sweetened Condensed Milk.*

The report records the bacteriological analysis of thirty-three rejected samples which were "blown" and showed definite evidence of pressure. Yeasts were found in 30 tins, gas-producing aerobes and yeasts in 5, true gas-producing anaerobes in 1, no yeasts or gas-producing bacilli in 2. Thus yeasts were present in 91 per cent., and the evidence demonstrates that the unsound condition is commonly due to yeasts, although yeasts are frequently met with also in sound tins. Examination of tins rejected although not definitely blown showed in some cases yeasts, bacilli and cocci, but the tins were mostly old or slightly defective and there did not appear to be any definite bacterial cause to account for the condition.

*Types of Organisms Isolated from Sweetened Condensed Milk.*

Sweetened condensed milk is never sterile. Yeasts, moulds, micrococci, anaerobes, gas-producing aerobic bacilli, sporing aerobic bacilli, thermophilic bacteria, and other aerobic organisms are often present. Micrococci are present in every sample of sweetened condensed milk and many are heat resistant, having survived the heating given to the milk before condensation. The chief types are staphylococci, streptococci, and diplococci, capable of multiplying in the condensed sweetened milk. They may be derived from the original milk or represent contamination during the manipulations. The anaerobes isolated did not decompose the sweetened condensed milk. This is not to be attributed to the presence of saccharose, since they behaved similarly in unsweetened condensed milk, but is due to physical changes consequent on concentration which make the final product an unsuitable medium for growth. The gas-producing aerobes isolated were all of the *B. coli* type but were unimportant as causes of decomposition. *B. coli* strains are not inhibited by the percentage of saccharose present, but they will not grow and ultimately die out in sweetened condensed milk, which, either from its viscous nature or from some other cause, is a medium unfavourable to their growth and vitality. Sporing aerobic bacilli were isolated from 92 per cent. of all tins examined and are almost universally present in sweetened condensed milk even when perfectly sound. While probably not a direct cause of tins becoming blown they may cause decomposition changes in milk, for their ability to liquefy blood serum and peptonize milk shows they are capable of decomposing proteins and are, therefore, potential causes of decomposition of milk; 40 per cent. saccharose is probably inhibitory to some extent, but the concentration of the milk is of more importance since even in unsweetened milk under aerobic conditions these sporing aerobes can multiply and produce acid, but they do not peptonize or even clot the condensed milk. The process of concentration of the milk has so altered its condition that the milk is no longer clotted or peptonized. As a cause of decomposition or of other abnormal changes in the milk, they seem to play either a negative, or at most a very insignificant, part. Possibly acting symbiotically with diplococci they may produce changes which neither strain could accomplish by

<sup>1</sup> Department of Scientific and Industrial Research, Food Investigation Board. Special Report, No. 13. Studies in Sweetened and Unsweetened (Evaporated) Condensed Milk. By W. G. Savage, M.D., B.Sc., and R. F. Hunwicke, B.Sc., A.I.C. H.M. Stationery Office. 4s. net.

127. Uterine Cancer without Haemorrhage.

J. W. Nappes (*Nederl. Tijdschr. v. Geneesk.*, July 7th, 1923, p. 35) states that the ordinary sequence of events in uterine cancer is leucorrhoea, which sooner or later becomes field, cancer is usually causes no pain, and it is not until the growth has invaded the neighbouring parts that pain is felt. Trochu, in his textbook on gynaecology, states that haemorrhage must be regarded as the first sign of cancer of the uterus, and Penzoldt and Stintzing, in their *Handbook of Treatment*, state that haemorrhage after the menopause is almost pathognomonic of uterine cancer. Boersma, in 1918, recorded two cases of extensive cancer of the uterus without haemorrhage, and Nappes now reports the following case.

The patient was a woman, aged 52, who had suffered from pain in the left thigh for 120 months without any relief from salicylates. On vaginal examination it was found that the cervix was tender and a very hard cervix was felt. There was no leucorrhoea and some tenderness in the left parametrium was detected. Per rectum an extremely tender tumour was found on the posterior wall of the uterus, which was fixed to the pelvis. A diagnosis of inoperable uterine cancer was made and confirmed by a biopsy which showed the appearance of an adenocarcinoma.

128. Single and Twin Tubal Pregnancy.

ACCORDING to L. B. AREX (Surg., Gynecol., and Obstet., J. med. 1923, p. 803), tubal pregnancy occurs in women who are about age and a half years older, on the average, than the mean type of tubal pregnancy. About one-third of the patients are already pregnant, are already married, and have already borne children. The age of the patients ranged from 20 to 40 years, the average being 26 years 10 months. The duration of the pregnancy ranged from 12 to 36 weeks, the average being 20 weeks 4 days. The results of the pregnancy were as follows:

| Results                                   | Number of Cases | Percentage |
|-------------------------------------------|-----------------|------------|
| Successful                                | 1               | 3.3        |
| Spontaneous abortion                      | 1               | 3.3        |
| Induced abortion                          | 1               | 3.3        |
| Stillborn                                 | 1               | 3.3        |
| Living child                              | 1               | 3.3        |
| Maternal death                            | 1               | 3.3        |
| Fetal death                               | 1               | 3.3        |
| Living child and maternal death           | 1               | 3.3        |
| Living child and fetal death              | 1               | 3.3        |
| Living child and maternal and fetal death | 1               | 3.3        |
| Total                                     | 30              | 100        |

The author states that the results of tubal pregnancy are not as favorable as those of intra-uterine pregnancy. The results of tubal pregnancy are as follows:

| Results                                   | Number of Cases | Percentage |
|-------------------------------------------|-----------------|------------|
| Successful                                | 1               | 3.3        |
| Spontaneous abortion                      | 1               | 3.3        |
| Induced abortion                          | 1               | 3.3        |
| Stillborn                                 | 1               | 3.3        |
| Living child                              | 1               | 3.3        |
| Maternal death                            | 1               | 3.3        |
| Fetal death                               | 1               | 3.3        |
| Living child and maternal death           | 1               | 3.3        |
| Living child and fetal death              | 1               | 3.3        |
| Living child and maternal and fetal death | 1               | 3.3        |
| Total                                     | 30              | 100        |

The author states that the results of tubal pregnancy are not as favorable as those of intra-uterine pregnancy. The results of tubal pregnancy are as follows:

| Results                                   | Number of Cases | Percentage |
|-------------------------------------------|-----------------|------------|
| Successful                                | 1               | 3.3        |
| Spontaneous abortion                      | 1               | 3.3        |
| Induced abortion                          | 1               | 3.3        |

129. **Pelvic Haematoma originating in the Corpus Luteum.**  
N. O. LORROS (*Arch. f. Gynäk.*, March 17th, 1925, p. 194) describes two cases in which patients aged respectively 26 and 35 suffered from pain and uterine haemorrhage following a retardation of the menses; laparotomy appeared to confirm the diagnosis of ectopic pregnancy with retro-uterine haematoma, but further examination of the excised adnexa of one side showed the haemorrhage to have come from a blood-disseminated and perforated corpus intumescens. There was an absence of leucocytic infiltration, the conclusion was drawn that in these cases the bloodleak arose from the bursting of not an ordinary corpus intumescens as such, but of a corpus intumescens which was cystic in its composition and in its structure, and in which the bloodleak was ectopic in position, not in its view as to the fact that the epithelial lining was recognizable microscopically in its entirety and showed but little change as is described in the exact source of such retro-uterine haemorrhaging. The exact source of such retro-uterine haemorrhaging is not susceptible of clinical diagnosis, and is likely always to be confused with ectopic pregnancy.

130. Premature Detachment of the Normally Situated Placenta.

F. J. TEES (*Canadian Med. Assoc. Journ.*, June, 1923, p. 406) records four cases of volvulus of the small intestine, and in considering the etiology of the condition a variety of explanations are given. The volvulus is usually ascribed to the presence of adhesions or to abnormalities in the length of the mesentery or of the bowel, and it must be admitted that in instances to occur where this is obtainable, but it is doubtful if these structural changes account for the majority of cases. It has been pointed out that a much higher incidence of volvulus exists among races bordering on the Baltic Sea; this may be due to the degeneration of these peoples or it has been suggested that they have longer intestines than English, French, or German subjects. There is no doubt that that disturbance in peristalsis plays an important part in producing volvulus. In the author's cases there was not any undue lengthening of the mesentery or evidence of adhesion, but all our cases seemed to show a distal bowel inactive from one cause or another, while the proximal bowel was thrown into unusual peristaltic activity, thus producing a strangulation which would appear arranged in a spiral manner, which imparts a screw-like action to peristalsis and may aid in the production of the condition. The conclusions arrived at by the author are that greater emphasis must be placed on the disordered peristaltic action leading to a relationship between adjoining segments of bowel, unusually fixed, and it is suggested that the teaching must be reversed in many instances and can occur only in the presence of a pathological abnormality.

131. *The Flow of Lymph from the Mesocaval Angle.*  
L. R. BRANTHWAITE (*British Journal of Surgery*, July, 1923, p. 7) points out that there are three gastric fistigmas which enable the lymphatic system to drain the stomach, and to recognize a diseased appendix almost with certainty, whilst it is still on of sight. The three fistigmas are: pyloric spasms, pyloric constriction, and gastro-jejunal fistula. The first two may be recognized by the angle of the gland around the inferior mesenteric artery, whilst the third is clearly defined, the main lymphatic trunk being enlarged. Experiments were carried out on the dog to show that lymph vessels were carried in the omentum, and that the abdominal cavity was a reservoir for lymph. In considering the results of these investigations on the cases of lymph vessels and on the lymph node, in connection with cancer, it was ascertained that the omentum was a reservoir for lymph, and that the lymphatic system was a drainage system for the lymphatic system. The lymphatic system was a drainage system for the lymphatic system, and the lymphatic system was a drainage system for the lymphatic system.

## Pathology.

1922. This gives the remarkably high incidence of 0.85 per cent. In the same period there were only 11 cases of placenta previa. The former accident must therefore be considered as the more important, at any rate from a numerical point of view. The age also showed that the frequency of this type of accident increased uniformly with age. Among women between the ages of 20 and 23 the incidence was 0.76 per cent, whereas among those aged 40 or over it was as low as 0.35 per cent. Only in a very few cases could the comparison be made simply on factors as birth weight and shortening of the cord, but no material similarity, and as many as 12 slices of the placenta were found responsible for the accident. Among the six of the infants survived; but among the 20 severe cases, the infant died. One of the 10 who joined which the mother survives is that in severe cases the mortality is about 40 per cent—that is, decided on the basis of the infant's survival occurs for any given treatment can be adopted. In risk with the mother in the hope that he may save the infant severe cases, therefore, the physician should take no great

capable of producing gas and causing blown tins. In the 47 rejected samples of unsweetened condensed milk examined the causes of unsoundness were sporing anaerobes in 3, micrococci in 18, coccoidal bacilli in 5, yeasts in 1, gas-producing aerobic bacilli in 6.

#### Practical Considerations.

It is pointed out that the changes resulting from concentration are profound and not merely caused by deprivation of water. The milk is so altered that it becomes less suitable for bacterial multiplication. It is doubtful whether the temperature during the process is capable of ensuring a sterile product in every case. What is obtained is not a milk uniformly sterile but one which leaves a variable percentage of tins containing living organisms. In view of the fact that comparatively little differences in the temperature of sterilization and slight changes in acidity may yield a coagulated useless product, the tendency is for manufacturers to under- rather than over-process the milk. Since decomposition is nearly always due to non-sporing types the manufacturer has essentially to guard against the survival of non-sporing bacteria, especially more resistant types of micrococci, and against admission of air through minute leaks which may enable dormant forms to multiply and cause decomposition changes.

### STATISTICS OF ANTIRABIC INOCULATIONS IN INDIA.

LIEUT.-COLONEL J. W. CORNWALL, M.D., I.M.S., of the Pasteur Institute of Southern India, Coonoor, Madras, has presented to the Congress in Strasbourg a statement as follows, giving the statistics of the results of antirabic inoculations carried out at the Institute.

The majority of the patients have been given the following treatment: 1 per cent. fixed virus suspension in 0.85 per cent. NaCl with 0.5 per cent. phenol. Each person receives 5 c.cm. once daily for fourteen days, injected subcutaneously over the abdomen, 2½ c.cm. on each side.

The Institute has been working for sixteen years and 28,898 persons have received the full treatment mentioned above:

|                                                                      |                      |
|----------------------------------------------------------------------|----------------------|
| Total number treated: 28,898.                                        |                      |
| Died during treatment ... ..                                         | 45 = 0.15 per cent.  |
| Died less than fifteen days after the completion of treatment ... .. | 78 = 0.27 per cent.  |
| Died more than fifteen days after the completion of treatment ... .. | 200 = 0.70 per cent. |
| Total mortality ... ..                                               | 323 = 1.11 per cent. |
| Percentages of failures ... ..                                       | 0.7                  |

In Madras the bite was inflicted in most instances by dogs (95.4 per cent.), and only rarely by jackals (2.7 per cent.). In other parts of India the proportions are different, a much larger number being inflicted by jackals.

#### The Infectivity of Rabid Dogs.

Certain dogs, proved rabid by laboratory tests, have bitten many people without infecting any of them. Other dogs, also proved rabid by laboratory tests, have infected the majority of the people whom they bit. Probably different strains of the virus of rabies differ in infectivity.

When the criterion of the infectivity of the biting animal is the death from hydrophobia of one of the persons bitten, the risk run by the other persons bitten by the same animal who have received no treatment can be estimated. A number of such instances has been collected by the Pasteur Institute of Southern India. The bitten persons had received no treatment:

|                                 |     |
|---------------------------------|-----|
| Number of persons bitten ... .. | 423 |
| Deaths from hydrophobia ... ..  | 148 |
| Mortality per cent. ... ..      | 35  |

So it may be concluded that in Southern India about 35 per cent. of persons bitten by rabid dogs which are actually infective will, if untreated, develop hydrophobia and die. No account is taken in this estimate of the position, number, or severity of the bites inflicted.

#### The Influence of Prophylactic Treatment.

The influence of prophylactic treatment in preventing the onset of hydrophobia can be estimated only by collecting a long series of similar groups of persons bitten by rabid dogs, the infectivity of each dog being proved by the death from hydrophobia of at least one of the persons bitten by it. If some of the persons in each group receive preventive treatment and some do not, the value of the treatment can be estimated.

A less accurate but still a useful way of arriving at a valuation of antirabic inoculation is to take only those instances in which a presumably rabid dog has bitten several persons of whom some accept the treatment and some refuse. Both the treated and the untreated are kept under observation for a period of months. The treatment given at the Pasteur Institute of Southern India when first investigated over a number of years shows the following result:

|                                   |               |
|-----------------------------------|---------------|
| Number of persons observed ... .. | 2,174         |
| Treated ... ..                    | 812           |
| Deaths among treated ... ..       | 2.9 per cent. |
| Untreated ... ..                  | 1,362         |
| Deaths among untreated ... ..     | 6.2 per cent. |

So we may conclude that our treatment saves one out of every two persons who would otherwise have developed hydrophobia and died.

The ordinary statistics published by Pasteur Institutes cannot be used for estimating the value of preventive antirabic treatment.

#### ROYAL MEDICAL BENEVOLENT FUND.

At the last two meetings of the Committee sixty-one cases were considered and £547 18s. voted to thirty-nine applicants. The following is a summary of some of the cases relieved:

Daughters, aged 51 and 46, of M.D.St. Andrews who died in 1871. Through the death of a brother, whose pension ceased at his death, they expect that their income will not exceed £30 per annum each. The elder sister received £30 from sewing and the younger £20 as a journeyman. Voted £20.

Daughter, aged 54, of M.R.C.S.Eng., 1863, who died in 1871. Applicant was a school nurse, but is now suffering from familial degeneration of the cerebellum. Her brother will allow her 5s. a week and friends have given her £5. She received board and lodging in return for light house-keeping duties. Voted £18 in twelve instalments.

Widow, aged 63, of M.R.C.S. who died in 1920, has only earned £5 during the last twelve months. She has had an offer to go abroad to look after some children but has not the means to go. Voted £5.

Widow, aged 49, of M.R.C.S. who died in 1910. A brother-in-law who has helped the applicant to the extent of £15 per annum is unable to continue this assistance. This money was used to pay the applicant's daughter's travelling expenses to and from school, and the applicant applied the fund for a grant for this purpose. Voted £10 in two instalments.

Daughter, aged 41, of M.R.C.S., L.R.C.P. who died in 1913, is now in a sanatorium and asks the Fund to help with maintenance. Her father died leaving a bankrupt estate. Voted £18 18s. for sanatorium treatment.

Widow, aged 64, of M.D.St. And., F.R.C.S.Eng. who died in 1871. Applicant has a little house property which brings in about 35s. a week. She has been suffering from diabetes for years, and is now in hospital under treatment at £1 1s. a week. Voted £10.

Widow, aged 74, of L.S.A., L.R.C.P. who died after a short illness in February last. House and furniture had to be sold, and after mortgaging had been paid and all expenses applicant estimates that her income will not exceed £35 per annum. At present her board and lodging costs £1 1s. a week. Voted £18 in twelve instalments.

Widow, aged 53, of M.B.Lond. who died in 1912. Applicant, owing to physical inability, is unable to do private nursing continually. She is maintained and educated her daughter and is now hoping that her daughter will be able to secure a post. Voted £10 in two instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., M.S., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild receives many applications for coats and skirts for ladies and girls holding secretarial posts, and suits for boys. The Guild appeals for second-hand clothes and household articles for the benefit of widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

The Dyestuffs Advisory Licensing Committee of the Board of Trade had before it during July 395 applications for licences to import drugs and makers of similar products and 50 to refer to British-made dyestuffs. Licences were granted to 246 applicants.

West Yorkshire Coalowners' Association, and were sympathetically received. Mr. Braine also has a scheme in hand for approaching the professional and business classes of the community, and this, it is confidently expected, will bring in a large sum annually. Referring to the prospect of the opening of the remaining large ward, which, as has been mentioned above, has now been carried out, Mr. Taylor told the meeting that this would involve an annual expenditure of at least £5,000. He also referred to the pressing necessity for greater accommodation for nurses, whose numbers tended to increase year by year, not only in connexion with the number of patients, but with the increasingly serious nature of the cases and with the development of the work. Though it did not come within the business at the annual meeting, it may be mentioned that at the last meeting of the board estimates were accepted for an extension of the nurses' home at a cost of some £12,500. This extension will provide more bedrooms, and also make more adequate accommodation for the training school. During the present year a bazaar was organized by the nurses and sisters at the infirmary, and realized the sum of upwards of £3,000. No more eloquent appeal could be made to the public than this most timely and unselfish effort.

## Scotland.

### MEDICAL ATTENDANCE IN RURAL DISTRICTS.

THE annual conference of the National Federation of Rural Approved Societies was held last week in the Royal Arch Hall, Queen Street, Edinburgh. A number of questions affecting the health of rural communities and village life generally were discussed and an address was delivered to the delegates by Sir James Leishman of the Scottish Board of Health. Sir J. Athelstane Baines, who presided, said that there was a community of feeling in villages, and they must remember that, from the point of view of insurance, neighbourliness tended to a certain laxity of administration. Thus, there might be an occasional tendency on the part of a doctor to keep a patient rather longer on the list than was necessary. The administration of benefit was undoubtedly less strict in the villages than in the towns. Mr. James Falconer, M.P., in moving the adoption of the annual report, congratulated the Federation upon the work it was doing. In regard to the question of unemployment insurance, he said that in Scotland they were out and out opposed to any attempt to bring the rural workers under the present Unemployment Insurance Act. It would be a tax levied on the rural workers of Scotland for which they would receive practically no benefit at all. Continuing, he said that the approved societies had received a definite pledge that they would be consulted before terms were arranged with the doctors. He thought the Insurance Act was a good friend of the doctors. The doctors, as a whole, were doing their work very well; and it was as much in the interests of the doctors, whose reputation as a profession stood very high, to have unreliable certification stamped out as it was in the interests of the societies. Sir James Leishman said they were faced with many industrial, economic, and financial problems, but the Insurance Act had stood not only the stress of this period, but also the terrible test of the war in a way that had surprised a large number of people. The medical referee system had been entirely satisfactory. Of 32,000 doubtful cases disposed of, 45 per cent. were found incapable of work and 55 per cent. were found capable and went back to work. He took it that there would be no increase in contributions and no extra grants, and if there were any proposals to find more money the societies would have to find the money themselves. The sum of 9s. 6d. for capitation fee, plus 6d. for Insurance Committee administration, would stand in the Act at the end of this year. He understood that the doctors were asking for a capitation fee of from 10s. 5d. to 10s. 9d., and the question would have to be faced before long. The vast majority of medical men were rendering good and efficient service; and, according to his information, the men out in scattered

rural areas had given, on the whole, better service than the town men, and the country practitioner deserved a little better treatment than the men in the towns.

### A REFORMED LOCAL HEALTH AUTHORITY.

The Scottish Board of Health's Consultative Council on local health administration and general health questions has submitted to the Board a report on a reformed local authority for health and public assistance. Unfortunately the chairman of the council, Sir Thomas Munro, county clerk of Lanarkshire, well known for the vast amount of public service he had done in Scotland, has recently died. The council had nineteen members, and the thorny nature of the subject is shown by the fact that five of the nineteen have found it necessary either to make reservations or to dissent from the report. There is little or no question about the need for reform; the difficulty is to get anything serious done where so many diverse views are held, so many interests affected, and local sentiment is so strong, at the same time that Parliament has so much other work to do. There are no less than 201 self-governing burghs in Scotland, 19 of them with a population under 1,000 and 108 more with a population under 5,000. Obviously such areas cannot individually provide the public health services required, in respect, for example, of water, drainage, infectious disease, hospitals, sanatoriums, and expert staffs, at the same time that the difficulties of combination are often insurmountable, especially where financial jealousies are concerned. The reform proposed is sweeping. The town councils of burghs with a population of 50,000 and over should be the public health authority; for the county area the county council containing representatives appointed by the town councils of burghs with less than 50,000 should be the local health authority. This would leave seven municipal authorities and thirty-three county councils. Apart from vested interests, probably the great majority of public health officers will agree that this small number is far better than the present absurd multiplicity, but it seems doubtful whether a bill to give effect to these proposals has much chance to become law, looking to all the influences which would be ranged against it. Perhaps the report, however, may have the effect of leading to some measure of much needed reform.

### EDINBURGH HOSPITAL STAFF CHANGES.

On his relinquishment of the charge of wards in the Royal Infirmary, Edinburgh, the managers of that institution last week appointed Sir David Wallace, K.B.E., C.M.G., to be one of its consulting surgeons, and on the motion of Dr. George Mackay placed on record their very high appreciation of his services to the institution. Mr. W. J. Stuart has been appointed one of the surgeons-in-ordinary to the Royal Infirmary and Mr. W. Q. Wood one of the assistant surgeons. The Directors of Chalmers Hospital have appointed Mr. Norman M. Dott assistant surgeon to that institution in room of Mr. W. Q. Wood. The Medical Committee of the Church of Scotland Deaconess Hospital has appointed Mr. J. M. Graham surgeon to the Deaconess Hospital, in room of Mr. W. J. Stuart, appointed to the Royal Infirmary, and Mr. Norman M. Dott assistant surgeon.

## Ireland.

### UNIVERSITY ELECTIONS IN THE NEW DAIL.

A MEETING of graduates of the National University, Ireland, adopted as candidates for the representation of the University in the new Dail, Mr. Michael Hayes, M.A., Professor John MacNeill, D.Litt., and Professor William Magennis. A committee to secure the election of these candidates was appointed and in the course of an appeal on behalf of the candidates has stated: Under present conditions stability of government and public security are the supreme necessities. Neither education, public health, nor any other vital

## PROCEEDINGS OF SECTIONS.

### SECTION OF RADIOLOGY AND

#### ELECTROLOGY.

S. GILBERT SCOTT, M.R.C.S., L.R.C.P., President.

### DISCUSSION ON MEDICAL DIATHERMY.

#### OPENING PAPER

E. P. CUMBERBATCH, M.A., M.B., OXON., M.R.C.P., LOND.

Medical Officer in Charge, Electrical Department, St. Bartholomew's Hospital.

Medical diathermy is now being used by a considerably larger number of practitioners than was the case two or three years ago, and although the results which follow this form of treatment are possibly less quick and dramatic than those which follow surgical diathermy, they are no less valuable. Medical diathermy can, in fact, produce therapeutic results which no other form of treatment can effect. Little has been written, however, on the subject in the medical journals in this country, but I hope that we shall hear at the present meeting the experience of those who have been using diathermy for non-surgical purposes. In opening the discussion I propose, first, to say a few words on the design of the present diathermy machines; second, to raise the question of the heating of the interior of the thorax and abdomen; and third, to bring before your notice certain morbid conditions for which the therapeutic properties of diathermy have been less used, although encouraging results have been obtained by certain workers at home and abroad.

With regard to the diathermy apparatus I feel that we need larger and more powerful machines. The machines at present made have often to be used "all out," and give their maximum output of current. This leaves no reserve of power for use on occasions when the sensitive part of the machine—the spark-gap—is not in its best possible condition, but cannot at the time be disassembled for cleaning. But the need for machines of greater power is more urgently felt when electrodes of large area are used. When these electrodes measure, say, 8 by 4 inches, the current density will be very low and the skin in contact with them will be only moderately heated. If, however, we wish to apply diathermy to the abdomen considerably larger electrodes must be used and the skin will be warmed very little, while the contents of the abdomen will probably, for reasons to be given later, undergo no rise of temperature. The spark-gap also needs further improvement. The original type, working in air with the plates separated by mica washers, becomes too hot with long use, and the current applied to the patient diminishes to a small value. The width of the gap cannot be adjusted without disassembling the parts, and the mica washers are sometimes pierced by the sparks. Gaps in an atmosphere of coal gas do not overheat, and those which can be regulated while the machine is working are preferable. Scott, however, accomplishes, and should be removed after the machine has been in operation for ten hours. It would be an improvement if the portions of metal between which the sparks pass could be detached and replaced from time to time. The surface becomes irregular and is gradually lost. I should like to learn the experience of those who have used gaps containing spirit. Does the gap overheat after some hours of continuous use, and does the metal unduly corrode? When the diathermy current is directed through the abdomen it has little resistance to overcome. Its path is

broad and its resistance low, while the abundant blood supply of the abdominal organs tends to conduct away the heat which is generated in them by the current. The statement that it is possible by means of the diathermy current to raise the temperature of any organ at any depth must be critically examined in the case of the abdominal and thoracic organs. On one occasion I placed a thermometer in a sinus that led to the region formerly occupied by the kidney, which had been removed for pyonephritis. The diathermy current was then passed anteriorly through the abdomen along the region containing the bulb of the thermometer. Large electrodes, measuring 8 by 4 inches, were used, and a current of 1.2 amperes was passed for twenty minutes. Although the skin was made as hot as the patient could bear without discomfort the thermometer in the sinus showed no rise. In this connection must be mentioned, however, certain experiments by Fürstberg and Schömel. The diathermy current was passed anterior-posteriorly through the abdomen, by way of electrodes measuring 8 by 12 inches, so as to include the stomach in its path. The temperature of the stomach was measured by a special instrument which was introduced into its interior. This contained a platinum spiral enclosed in quartz. The resistance of the spiral at different temperatures indicated the degree of heat in the interior of the stomach. The maximum rise obtained was 0.4° C. This was obtained with a current of 0.3 ampere. With a current of 2 amperes a rise of only 0.1° C. was obtained. This apparently paradoxical result was also obtained in animals. If the animal was afterwards killed and the circulation thereby stopped a stronger current produced a higher temperature. It is probable that in the living subject strong heating of the sensory nerve endings in the skin caused a reflex dilatation of the vessels of the stomach, so that the additional heat was more rapidly conducted away. These results were obtained in normal subjects. In disease the conditions are different, and different results might be obtained. There is clinical evidence, to which I shall refer presently, which shows that diathermy is productive of good in certain morbid conditions of the abdomen. One certain conclusion can, however, be drawn—namely, that dosage is of extreme importance. It must not be assumed that the maximum current and maximum heat produce the best effects. When the diathermy current is passed through a mucous membrane the relatively low resistance of the latter requires the application of a stronger current to produce the same degree of heat. On one occasion I applied diathermy to the prostate by way of an electrode placed in the rectum. The surface of application of the electrode was not more than one square inch, and although the machine was working at full power and gave a current of 2.5 amperes the patient said that he felt only moderate heat, and the thermometer indicated only 104° F. I shall now speak on the uses of diathermy in certain diseases. One of these is that due to infection by the gonococcus, and as my co-worker, Dr. Robinson, will speak on this subject later I shall leave the description of that method and results to him. I may say, however, that I first obtained an indication of the value of diathermy for the treatment of gonococcal infection in two cases of arthritis, in 1913. The results were so good that other cases of gonococcal arthritis were treated by the same method and, later, cases of similar infection of other parts. The treatment of such cases now forms a considerable part of the work of my department at St. Bartholomew's Hospital. There are other diseases in which good results have been obtained by certain workers by means of diathermy, and I should like to hear the experience of any of those present to-day. Among these diseases may be mentioned angina pectoris. Those who have read Nagelschmidt's work on diathermy may remember the excellent results which he claimed in this disease; after courses of treatment some of the patients remained free from attacks for months or years. I have not had the opportunity of treating a case myself, but I remember one patient who suffered from arterio-sclerosis and precordial pain. The latter was at once relieved by the application of diathermy to the heart.

in reviewing the activities of the two associations, said that there could be no breath of controversy regarding their objects, and there was every reason to expect that they were now established on a permanent footing as a powerful beneficent agent in time of peace.

#### THE CHEMICAL EXAMINER'S DEPARTMENT IN MADRAS.

The report for 1922 of the chemical examiner to the Government of Madras, Major Clive Newcomb, I.M.S., contains some interesting notes on medico-legal investigations. In 220 cases of suspected human poisoning, poison was detected in 108 (49.1). Mercury was the poison most commonly found (thirty-two cases), arsenic second (twenty-three cases), and opium third (nineteen cases). Of the less common poisons there were two cases of poisoning by cyanide, one by iodine, one by caustic soda, one by carbolic acid, and one by quinine and ergot. In four cases a poisonous alkaloid was extracted from the viscera, the exact nature of which the chemical examiner was unable to determine. The number of articles examined for blood or other stains was 1,583, a larger number than in any previous year. A larger number of bomb cases than usual was received, and in one of these no fewer than 400 bombs made to explode on percussion were sent. The number of general analyses performed during the year was 570, 144 of them for the Customs Department. Major Newcomb notes the regularity with which murder cases occurred throughout the year. The monthly records of murder cases for the past ten years were examined, but no seasonal variation could be detected. The number of cases of poisoning and blood-stains received from 1912 to 1921 was 4,645, an average of 38.7 a month; the month with the highest average number was July, with 43, and the lowest November, with 34.

#### WOMEN'S HOSPITALS IN INDIA.

A pamphlet on the planning and equipment of women's hospitals in India has been published by the Council of the Countess of Dufferin's Fund. Few of the hospitals staffed by women in India are Government institutions, the only Government hospitals being the Cama Hospital at Bombay, the Dufferin and Lady Lyall Hospitals at Agra, and the Victoria Hospital at Madras. Other hospitals have been built by private generosity, assisted by charitable funds or aided by local authorities, or have been built and are conducted by missionary societies. The importance of creating an endowment fund when establishing hospitals of this type is emphasized, and plans are appended for the construction of different types of hospitals, ranging from a zenana hospital of eighty beds to a dispensary with an emergency ward of four beds.

#### MINTO NURSING ASSOCIATION.

In the report of the Minto Nursing Association for 1922 the secretary states that subscriptions have fallen off considerably, and that with a view to easing the finances it was decided to restrict as much as possible the expenses incurred on account of passages to Europe, and to engage as many suitable candidates for the nursing staff as could be procured in India. The association was founded in 1906 as the result of an appeal made by Lady Minto both in India and England; the endowment fund has gradually increased, and with the assistance of a Government grant homes for nurses have been established in seven provinces of India and in Burma. The total number of cases attended during 1922 was 1,537, as against 1,463 in 1921.

#### LADY READING HOSPITAL, SIMLA.

The foundation stone of the Lady Reading Hospital for Women and Children at Simla was laid by the Countess of Reading on June 15th. The hospital is designed to provide fifty to sixty beds, with up-to-date equipment and an efficient staff, to meet the medical needs of Indian women and children particularly in Simla and the surrounding districts, but also in other parts of India. It is well endowed to meet immediate requirements out of the Lady Reading Women of India Fund. Sir Muhamed Shafi paid a tribute to Her Excellency's unceasing care and attention to institutions maintained for the welfare of Indian

women; for many years those in authority had been very anxious for the establishment of a separate institution for Indian women, but many difficulties had stood in the way; it had been left to the energy of Lady Reading to carry out the foundation of an institution long overdue. The Viceroy said that the object of establishing the hospital at Simla was that it should be in as healthy a climate as could be found in India; it would provide an admirable training school for Indian nurses. The efforts of Lady Reading had been supplemented by the Simla municipality, who had shown a very commendable interest in the project by undertaking to provide 12,000 rupees annually towards its upkeep.

#### COMPULSORY VACCINATION IN HYDERABAD.

Hitherto there has been no proper system of registration of births of children in Hyderabad, but it is known that the mortality from small-pox among children is large. The Nizam has now issued firmans commanding that the system of registering births and deaths in the State should be put on a proper basis in consultation with Colonel B. J. Singh, I.M.S., Director-General of the Medical Department, and that the vaccination of children under the age of one year shall be compulsory throughout his dominions.

## Correspondence.

#### THE WORK OF COTTAGE HOSPITALS.

SIR,—In your leading article (July 21st) on the work of the voluntary hospitals, you refer to the phrase in Sir Napier Burnett's report that "The question arises whether the cottage hospital idea has not been rather overdone." There is no question as to the accuracy of Sir Napier's figures or the value of his report, but I regret that he has given the weight of his great authority to such a statement.

There is no doubt that in some places cottage hospitals are not used so effectively or as fully as they might be, but the statement: "No fewer than 1,839 cottage hospital beds (in England and Wales, excluding London) were unoccupied on an average all the year round," requires careful consideration. The decline in the number of beds occupied is not confined to Group C, cottage hospitals, only, although much more marked there.

In Group B, hospitals of 30 to 100 beds, the average dropped in the three years from 76.7 to 73.0, but this period is probably too short a time from which safely to draw any conclusion.

In Group A, hospitals over 100 beds, there is an average of 17.83 beds unoccupied—that is, 3,737 beds.

In Group B, there is an average of 26.99 beds unoccupied—that is, 2,276; so that in Groups A and B together there are over 6,000 beds "unoccupied on the average all the year round."

In Group C, the average of unoccupied beds is 40.77—that is, 1,864 beds.

Now it is admitted that in the large hospitals a percentage of only 18 unoccupied beds indicates a high pressure of work, and it is well known that the causes which necessitate a certain number of unoccupied beds have more effect the smaller the institution, so that in Group B the average is higher than in A, and in Group C higher than in B.

If we allow the same average for hospitals with less than 30 beds as we find in hospitals with less than 100—that is, 27 per cent.—we see that there would be 1,234 that is, 27 per cent.—we see that there would be 1,234 cottage hospital beds unoccupied on the average in a year, and it will be admitted that none of these beds is available for other cases than those normally admitted to the hospital; otherwise if our large hospitals have such long waiting lists why do they not use the 6,000 beds that "on an average remained idle throughout the year 1922"?

I have used this phrase "remained idle throughout the year 1922," which occurs in much the same form in various parts of the report, although I do not agree with it. I am quite sure that its author did not intend it to be misleading, but the impression it gives one is that the same beds were empty throughout the whole of the year. The last paragraph but one of Sir Arthur Stanley's introduction supports my contention. The fact is that these beds are only empty

prove disastrous to a candidate innocent enough to accept it. In so far as it is true it can only mean that examiners in medicine neglect their opportunities and responsibilities, and this, I am sure, you would be reluctant to propose.—I am, etc.,

London, W., Aug. 6th.

C. O. HAWTHORNE.

### REPRODUCTION AND THE SHEDDING OF ANTLERS IN DEER.

SIR,—Are we fully justified in drawing such a direct and intimate connexion between those two processes as is done by Sir William Macewen in his address to the International Society of Surgery (BRITISH MEDICAL JOURNAL, July 21st, p. 91)? Most animals fight each other almost at any time of the year; still in the breeding season (usually in spring) they are more pugnacious, and are then at their best in fitness, physique, and beauty; but the tegumentary adornments such as the mane of the lion, the clean and glossy skins of other animals, and the beautiful plumage of male birds are there to make the males more attractive to the females, and not for fighting purposes. Why then should the beautiful antlers of the deer be thought of in any other light?

The natural weapons of deer are fleetness, ability to fight with their forelegs and feet, or occasionally with their mouth, and when the velvet permits with their foreheads like oxen. As a fighting machine the antlers are clumsy, and for months annually are out of action. Besides, some stags have no antlers; in some deer they are present in both sexes, and there is an evident connexion between the size of the antlers and the quantity of hair on the bodies of the deer, and as a matter of observation in actual combat the polled stag is often more than a match for the antlered stag.

The peculiarity of the development of the embryo, the duration of gestation, the breeding season being in autumn, instead of spring, are other characteristics of deer, as well as the absence or presence of antlers and their shedding, and are unusual or abnormal.

If, as Sir William suggests, the testes be the *fons et origo* of the antlers it seems most extraordinary that their evolution, growth, and decay should coincide with the most quiescent state of these glands; surely they cannot be active and inactive simultaneously. Do we not hear too much about inhibition and suppression to the exclusion of more natural laws? Might we not more fitly compare the shedding of the antlers to the annual casting of the skins of snakes, the moulting of birds, or loosing of hair, hoof, nail, or other cutaneous appendage in animals, and look on all these phenomena as Nature's effort to assist excretion, continuously or at certain regular periods, by throwing off from the blood certain salines or products of nitrogenous metabolism, many animals having their own particular method?

Physiologically the falling of leaves from trees may reasonably be compared to the shedding of antlers, and in both, when the process is allowed to occur naturally, a beautiful clean scar is left. Here again, in my opinion, both leaves and antlers come and go for the beauty, health, and life of the tree and animal respectively, for self-preservation is more important than either reproduction or the herd instinct.

In recent years too much importance and attention have been assigned to matters reproductive, and a hint from one in the professional position of Sir William Macewen might become an obsession in the mind of a weaker brother.—I am, etc.,

T. JOHNSTONE, M.D., M.R.C.P.

Harrogate, Aug. 6th.

### PATHOLOGY OF MALIGNANT DISEASE.

SIR,—The difficulty in obtaining cultures or transplants from malignant tissue is evidence that the conditions of viability of this tissue or of a possible parasite which gives rise to it are narrowly defined. We should be able to determine these conditions more accurately, and vary them in a sense adverse to the disease without waiting for the demonstration of an ultimate cause.

For instance, the chemical reaction of the fluids of a malignant tumour is not usually considered. There is some

reason to think that the reaction is acid, and we can neutralize carbonic or other acid by injections of a solution of sodium carbonate as directed by Fischer in his book on oedema and nephritis; possibly an even more effective result may be obtained by using a calcium base.

Again, malignant tumours are anaerobic; repeated injections of oxygen in the tissues near a tumour must produce a powerful effect, both local and constitutional, so that if the injections have to be made some little distance from the growth they will still be active, although the action will be indirect.

These questions are sufficiently practical to deserve the attention of those who have clinical material at their disposal and can work effectively at them.—I am, etc.,

RICHARD KERRY, M.D.  
(Montreal)

London, W., Aug. 11th.

### DENTISTRY AND MEDICINE.

SIR,—I have read with much interest the article by Sir William Willcox on "The clinical, pathological, and radiological aspects of infection of the teeth and gums" (January 13th, 1923, p. 53). It is well that men like Sir William Willcox are now recognizing the full importance of this subject. Many of us have been preaching the menace of oral sepsis, but presumably it still requires to be preached (though in some quarters the pendulum has swung to the opposite extreme and many ills are credited to quite innocent teeth). From the internal evidence of the paper alluded to I could flatter myself that Sir William Willcox had read the chapter on oral sepsis and its effects in my textbook on *Stomatology*. Whether this is so or not I am satisfied that the necessity for the writing of such papers arises from a weak spot in the medical curriculum. There is no systematic (compulsory) teaching for medical students on those border-line subjects lying between medicine, surgery, and dentistry. There should be a liaison lecturer—and then residents would recognize oral sepsis as "an actual potent factor in the causation of every-day disease."

In this University we have a short Course on Stomatology which it is compulsory for every medical student to attend in his fifth year. The course embraces:

1. Deformities of the teeth and jaws, including cleft palate.
2. Inflammatory conditions of the gums, mucous membranes, caries of the teeth—diagnosis and treatment.
3. Fractures and dislocations of the jaws.
4. Ankyloses of the jaws.
5. Oral sepsis and its effects, and conversely the manifestation of systemic diseases in the mouth.
6. Reflex neuroses and neuralgias.

The results of this class have been eminently satisfactory; the students are keen and take a live interest in the subject. The following are the questions set at the last examination:

1. Enumerate the various methods of treating cleft palate and give the indications for the use of each method.
2. Differentiate between dental myelitis (exposure of the pulp) and periodontitis. Outline palliative treatment for each condition.
3. Oral sepsis: classify secondary infections, and give examples of each.
4. Enumerate fluid swellings of the jaws. From what tissue is each derived? Give the chief diagnostic characteristics and indicate treatment in each case.

My class this year was composed of some seventy students, and I have no hesitation in saying that 80 per cent. of the answers were better than one would expect in a final qualifying dental examination.—I am, etc.,

H. P. PICKERILL, C.B.E., M.D.

Dunedin, New Zealand, May 25th.

### THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

SIR,—Surely Dr. Cameron Kidd's colleague must have misinterpreted his final "instruction"—"If you find vesicles on the palms of hands and soles of feet you may call it small-pox"? (BRITISH MEDICAL JOURNAL, August 4th, p. 208). As it stands, anything more misleading as a diagnostic criterion for small-pox it would be difficult to find.

It seems such a pity and so unnecessary that these half-truths should still be circulated and pass as current know-

Dr. AGNES SAYLE (London) recalled her experiences of local diathermy for the treatment of gonorrhoea in women. As long ago as 1911 she treated a case of gonorrhoea, having previously discharged from the cervix, by Sloan's method of local ionization with copper. In those days she gave too small doses, and hence the cure was delayed and the result took longer to bring about. That patient, however, was cured, and had a perfectly healthy child within a year. Within the last year she had two cases in her private practice in which profuse gonorrhoeal discharge responded well to a treatment of combined ionization and diathermy.

[illegible]

Dr. FLORENCE STROCK (Bournemouth) asked whether diathermy had been found altogether satisfactory for the treatment of chilblains. In her experience cases did well for the moment, but the condition recurred, simply because the original cause had not been tackled. Those who practised diathermy were hampered by getting only end-results in a great many cases. With regard to the tonsillar infection mentioned by a previous speaker, she did not think it necessary to remove the tonsils surgically because with the ultra-violet treatment the condition could be dealt with without so much discomfort to the patient.

Dr. KONIKOFF, in replying on the discussion, said that he had had one case of salpingitis with very definite infection of the cervix, and he had continued to treat that case by the ordinary methods of treatment of the cervix, and eventually the salpingitis cleared up. He had not had occasion to treat an acute case of prostatitis with retention of urine and so on.

merited a thorough trial.

The present routine methods of clearing up the infection than a more effective means of clearing up the infection they had as yet difficult to be convinced that in diathermy they had opportunity. While the results reported were excellent, it was in both acute and chronic conditions at the earliest opportunity. Dr. Robinson intended to try the methods of Dr. Robinson processes than the heat alone. Before pronouncing judgment mentioned, there must be other factors in the curative static infection in a joint. As several speakers had referred to the original focus alone would cure the meta-heats alone would cure the condition, and that application in foot of infection it was difficult to be convinced that absolute processes such as chronic prostatitis with closed-resistant organisms complicated the lesions. In chronic the tissues were destroyed and before other and more heating to the tissues would kill the gonococcus then it tried? If in these acute processes the application of deep had his results been in those cases in which he had tried Day Dr. Robinson tried it in such acute cases, and what frequency of micturition or retention of urine—in cases, say, of salpingitis, and in cases of ophthalmia neonatorum, gross cases as prostatic abscess or vesiculitis associated with irritate but acted as a mild sedative one would be inclined to think that the field for its use would be greatest in such statement of Dr. Chamberlaine that diathermy did not weeks with much simpler methods of therapy. From the unusual for this condition not to subside in less than two diathermy would act well in epididymitis, but it was quite were disappearing. One could quite appreciate how results of diathermy in anterior and posterior urethritis, involved in these cases, and yet the speaker admitted that the was a recognized fact that the posterior urethra was always themy to the prostate cleared up the condition, when it like to inquire into was how the local application of diathermy to the metacervical lesion. Another point which he would up the cervix or in the prostate was so effective in clearing account to see how treatment of the original focus only in cocci from the lining membrane. It was difficult on this many of the acute cases it was possible to isolate the gonococcus from the lining membrane. It was difficult on this the great majority of gonococcal joint conditions, as in the great majority of gonococcal joint conditions, as in algias he (Mr. Lees) could not agree that this was true of arthritis, Dr. Robinson had stated that the joint condition was chiefly a toxæmia. While this was so in the early to extraneous reinfection? In discussing the cases of infection which the deep heat had not reached, rather than recrudescence of the disease was due to tubal and uterine as being specially resistant, was it not possible that the blood of all these cases was examined by complement fixation test, as, if not, these methods might possibly improve blood of all these cases was examined by complement fixation test, as, if not, these methods might possibly improve mentioning treatment were examined by culture and if the would like to ask him if the discharges before com-

in convincing all medical men that their own charities must be brought out of the rut of secondary considerations and made to rank among those which require dealing with. The amount of subscription required should not prove to be anything approaching a deterrent, for it cannot really be assumed that an average subscription of 10s. 6d. would financially complicate anybody's pocket, and, so far as concerns members of the British Medical Association, the forwarding of this need not involve any extra effort as it can be included in the cheque for the annual subscription.

I believe the necessary education of the profession involves organized effort, and that any campaign in this direction can only be successfully undertaken with the help of the British Medical Association. I further believe that the first step to take is to sweep away the differences of opinion respecting the management of the fund, and that this could be effected by resuming the interrupted conference of 1922. In this direction I would make the suggestion that an invitation to recommence the sittings might, on this occasion, very appropriately emanate from the Governors of the fund.

The letter from Dr. Clarke is very practical, and reveals a valuable source of help which promises good results if properly managed and developed. Organized effort would see to this.—I am, etc.,

Manchester, Aug. 14th.

W. F. DEARDEN.

#### MEDICAL MAGISTRATES.

SIR,—In the important discussion on mental deficiency which took place in the Section of Medical Sociology at Portsmouth last month, and is recorded in this week's JOURNAL, there is a point which is not referred to by any of the speakers to which I wish to call the attention of the public and profession—namely, the desirability of having on every magisterial bench at least one medical man.

There is a considerable number of cases brought before the justices in which medical knowledge and experience are required for the full and just treatment of the person charged.—I am, etc.,

W. J. TYSON, M.D., F.R.C.P.,  
Chairman of the Elham Division of Justices  
for Kent.

Folkestone, Aug. 11th.

#### TREATMENT OF VENEREAL DISEASE.

SIR,—With reference to the letter from Sir John Collie on this subject in your last issue the National Council for Combating Venereal Diseases wish to express their very grateful thanks to Sir John Collie for all the trouble he took in getting this bill, drafted and promoted by it, through the House of Commons.

The same bill in the last Parliament became an agreed measure, and only failed of becoming law owing to the sudden dissolution. Sir John Collie was kind enough to undertake to father it at its reintroduction in the present Parliament, and as an agreed measure it passed the House of Commons. The thanks of the Council are also due to Lord Muir Mackenzie, who at the request of Sir John Collie undertook to shepherd it through the House of Lords.

The National Council has been working to obtain this legislation since 1919.—I am, etc.,

E. O. GRANT,  
Secretary.

National Council for Combating Venereal Diseases,  
102, Dean Street, W.1, Aug. 13th.

AN international vacation course will be held at Kissengen from September 3rd to 6th, when lectures will be delivered by Drs. Ueber, von Bergmann, von Noorden, and von Romberg.

DURING the ten years 1912-21 there have been released on parole from the Kalihi Hospital, near Honolulu, and on Molokai Island, 242 lepers as being no longer "a menace to the public health." The patients were required to report for examination, when it was found that 31 had relapsed, but 7 of these were discharged again on parole. Ten were released completely. Treatment for those who desire it is by chaulmoogra oil and its derivatives. The parole system has worked well and many lepers now go to the hospital voluntarily, thus obtaining earlier treatment and a consequent greater chance of improvement. About 70 per cent. of those released on parole were segregated for less than two years.

#### Obituary.

FREDERICK BELL, B.A. Oxon, M.R.C.S., L.R.C.P.,  
Humshaugh.

THE death of Dr. Frederick Bell of Humshaugh, which occurred on July 28th, robs North Tynedale of a notable personality. Only a brief sixteen years ago he first came to the district, but the large gathering from far and near which met at his funeral in the quiet churchyard at Humshaugh bore eloquent testimony to the way in which he had entered into the lives and affections of the people among whom he lived and worked.

Dr. Bell came of a medical stock and was the third generation of his family who had practised at Preston in Lancashire. He was the second son of the late Dr. Wm. Bell of that town, and was educated at Preston Grammar School and New College, Oxford, where he graduated B.A. with honours in science. His medical studies were pursued at St. Bartholomew's Hospital, and he took the conjoint diploma in 1888. He then returned to Preston as house-surgeon to the infirmary, and on the sudden and unexpected death of his father he took over the family practice. For eighteen years he worked strenuously and loyally in that capacity and was greatly respected in the town. Unfortunately his health, which was never robust, proved unequal to the strain and for that reason he sought a quieter sphere in the rather remote country district of Northumberland where Humshaugh is situated. Very soon the stranger from Lancashire became the trusted medical adviser of a wide area, and for years "Bell of Humshaugh" was one of the best known of the country practitioners in Northumberland. Those who know country practice best are well aware that the motor car and the Insurance Act have not really lightened the labour of the doctor, and Bell led a strenuous life, far too strenuous for his poor physique, and he was dogged by a series of grave illnesses, each attended by great anxiety to his family. But he either never would or never could spare himself, and in spite of the advice of his friends he worked "full out" almost to the end. His fatal illness, septic laryngitis, followed by septicaemia, was caught at the bedside of a patient who preceded the doctor to the grave. Bell had a very high sense of his responsibility to his patients, and he constantly strove not only to give them of his very best but to get the very best for them; this was the reason why he so often sent patients to hospital or called friends in consultation. But he was not content merely to hand over a case; he persistently followed his patients, and no practitioner more frequently attended operations or made inquiries about those of his flock who had temporarily left his care. This he did in winter as well as summer, in a district with a wretched train service, and having over twenty miles of the most exposed road (on the line of the Roman Wall) to traverse both going out and coming home. This same anxiety to do the best for his patients made him one of the most regular visitors at the scientific meetings and the post-graduate courses held in Newcastle. It is a sad coincidence that during his fatal illness he was unanimously elected president of the Newcastle-upon-Tyne and Northern Counties Medical Society. The British Medical Association also appealed to him and he threw himself energetically into the work of the Hexham Division, of which he was successively secretary and chairman. Of leisure he had none, but his tastes were literary and the company of books and the fragrance of flowers beguiled odd half-hours and made him content with his arduous lot, while an earnest religious faith consoled him in many a trial.

He leaves a widow, one son—an officer in the Indian Army now with his regiment—and two daughters, the elder of whom has recently graduated with the desire and intention of helping her father in his practice.

No one in North Tynedale was more respected, and the whole countryside bemoans his loss, for everyone feels that men of his stamp can ill be spared. The funeral was very largely attended by representatives of all classes, including numbers of medical friends. Floral tributes, like the congregation, overflowed from the church to the graveside and were a token of the love which his patients bore him.

of acidosis—that is to say, it is a condition in which the alkaline reserve of the body is abnormally increased—while in alkalosis the excess of bases over acids in the circulation is so considerable that the physico-chemical reaction of the blood is shifted toward the alkaline side. In the following chart I have endeavored to represent schematically the relation existing between the alkaline reserve, the non-volatile acids, and the carbon dioxide content of the blood in the various conditions we are considering.

This diagram also indicates the principles on which the determination and estimation of acidosis or alkalosis are based. The reserve of alkali in the blood is now generally estimated by determining its combining power for carbonic acid under standard conditions, or, indirectly, by ascertaining the tension of carbon dioxide in the alveolar air; for, as will be seen from the diagram, the combining power of the blood for carbonic acid, and therefore the tension, or percentage, of the latter in the air of the lungs, are directly dependent upon the relation existing in the circulation between the non-volatile acids and the alkaline reserve. The carbon dioxide capacity of the blood is usually estimated in the laboratory by Van Slyke and Coulter's method. It is hardly suitable for general clinical work, however, and reliance is more commonly placed upon some method of determining the carbon dioxide tension of the alveolar air. The simplest and most generally useful, in my opinion, is that devised by Marriott.<sup>1</sup> The subject breathes in and out of a rubber bag of about 1,500 c.cm. capacity, into which has been previously introduced about 600 c.cm. of air, about four times in twenty seconds, emptying the bag at each inspiration. The inlet tube is clamped at the end of an expiration and the air in the bag examined, within three minutes, by bubbling a fine stream through a solution of sodium bicarbonate containing a suitable indicator, and comparing the resulting color with a set of standards marked to indicate the carbon dioxide tension. In the case of infants a smaller bag is used, of about 500 c.cm. capacity, and this is connected with a mask which fits tightly over the face. Crying during the collection of the sample is an advantage rather than a disadvantage, but must be avoided prior to the application of the mask, as it leads to a lowering of the carbon dioxide tension. The carbon dioxide tension in a normal adult at rest, as determined by this method, varies from 40 to 45 mm. Tensions between 30 and 35 mm. are indicative of mild acidosis. When the tension falls to 20 mm. there is serious danger, and in some cases as low as 10 or 8 mm. may be obtained. In infants the normal carbon dioxide tension is from 3 to 5 mm. lower than in adults. Purists may criticize the results obtained with Marriott's method, but if the findings are occasionally standardized, in order to detect deterioration of the solution, they are of great practical use.

Limitations of time will only permit of my referring to one other test for acidosis—the tolerance for sodium bicarbonate. This depends upon the fact that not more than 0.5 gram of bicarbonate per kilogram of body weight, by the mouth, is required to render the urine of a normal person distinctly alkaline in reaction, whereas 0.8 gram

may be needed in mild acidosis, and over 1 gram in more severe cases. This test has the merit of simplicity and is not particularly dependable for showing either the presence or the degree of an acidosis when it exists.

Let us now consider the theoretical conditions under which acidosis and alkalosis may arise. Depletion of the alkaline reserve will result when there is an excessive introduction from without the body of acids, as occurs in mineral acid or carbonic acid poisoning, or when an abnormal formation of acids takes place within the organism, the classical example of which is diabetic acidosis; it may also result from an excessive accumulation of the normal acid products of metabolism in the system owing to deficiency in the excretory functions of the kidneys, as is seen in interstitial nephritis; or it may follow an exceptional drain of bases, from the body, such as may be induced by profuse diarrhoea. Alkalosis, on the other hand, will occur if the intake of alkaline bases is in excess of the excretory capacity of the organism and exceeds the neutralizing power of the non-volatile acids of the blood and tissues, a condition which can be produced by overdosing with sodium bicarbonate; a similar condition would arise should there be an unusual small amount of acid formed in the metabolic cycle, but of this there is no convincing example; an increase in the alkaline reserve may also be caused by the passage into the circulation of the alkaline radicals produced when neutral salts are decomposed and the acid radicals are excreted, as takes place temporarily during the normal formation of hydrochloric acid in the stomach and gives rise to more permanent changes in pyloric stenosis; finally, a diminution in the oxygen of the blood may excite the respiratory centre and lead to an excessive loss of carbon dioxide through the lungs, and, as there is no parallel fall in the bicarbonate content of the serum, alkalosis will ensue—a condition which may be produced by voluntary hyperventilation or may be induced by breathing air with a diminished oxygen content, as at high altitudes. It is obvious, therefore, that acidosis, and to a less extent alkalosis, may be met with in a large variety of diseases, and that acidosis is not, as was at one time assumed, invariably dependent upon disturbances of carbohydrate metabolism.

Very little experimental work has been done upon the acid-base equilibrium of the blood during the early years of life, and a good deal of what has been published is contradictory. Xipell<sup>2</sup> has stated that a condition of "physiologic acidosis" exists at birth and that the carbon dioxide dissociation curve is 20 per cent. less than in adults. Marriott<sup>3</sup> found that in children under 1 year of age the reaction of the blood tends more toward the acid side, and that the alveolar carbon dioxide tension is lower than later in life, a reading of 35 mm. not being abnormal. On the other hand, Gehrm<sup>4</sup> came to the conclusion that there is no constant difference in the carbon dioxide tension, and found that, as a rule, a much smaller dose of sodium bicarbonate in proportion to the weight is required to render the urine alkaline in young children than in adults. The observations of Blaherwick<sup>5</sup> upon calves are of interest in this connection. It has long been known that cows normally excrete a strongly alkaline urine, owing no doubt to the nature of their diet, which commonly contains a large excess of basic elements; calves, on the other hand, which consume an approximately neutral diet of milk, usually excrete urine which is neutral or amphoteric to litmus. Judging from these facts we should expect calves to have a smaller alkaline reserve than cows, but Blaherwick proved that this was not the case, and that calves actually possess a larger alkaline reserve than grown cattle. He came to the conclusion, therefore, that a fundamentally different regulatory mechanism is functioning in the two cases. Whether there is an analogous difference between children and adults it is impossible to be sure at present, although the well known clinical fact that children are especially susceptible to acidotic conditions is suggestive, and when we consider the more rapid metabolism of the infant, with the constant changes in its tissues and body fluids caused by the need for growth as well as repair, it seems even more probable.

graduated M.D., R.U.I., in 1865; he took the diploma of L.R.C.S.Édin. in the same year. For nearly half a century he practised medicine in Sudbury and the surrounding district, but he had retired from practice some time ago. He was honorary consulting physician to St. Leonard's Hospital, Sudbury, having formerly been for a long period a member of the active medical staff, and at the time of his death he was chairman of the committee of management. For many years he was medical officer of health for the borough of Sudbury, and for Glemsford Urban District Council and Melford and Belchamp Rural District Councils. He was one of the senior members of the Sudbury bench of magistrates. He was an old member of the British Medical Association, an ex-president of the East Anglian Branch, and a representative. He was the contributor of a number of articles in our columns during the eighties. He was also ex-president of the Cambridge Medical Society.

We regret to announce the death, on August 8th, of Dr. MARY K. HELENE NEARY, aged 40, wife of Dr. John F. Neary of Blackheath. She was the eldest daughter of the late Dr. Thomas Griffin, Louisburgh, co. Mayo, and niece of the late Sir Peter Freyer. She received her medical education at the Cecilia School of Medicine, Dublin, and the Royal Infirmary, Edinburgh, and obtained the L.A.H.Dubl. in 1918. Dr. Neary served as resident medical officer at the Jenny Lind Hospital for Children, Norwich, for over two years, and subsequently entered into general practice at Stoke Newington and Blackheath. She was a member of the Lewisham Division of the British Medical Association and took great interest in the infant welfare scheme, for which she will long be remembered in Bermondsey, where she did a large amount of work in connexion with the movement. She greatly endeared herself to her patients by her kind manner and the confidence she inspired, and many will mourn her untimely death.

The death, from appendicitis, of Dr. K. I. S. SMITH, at the early age of 30, occurred at Sunderland on July 20th. Dr. Kirtan Ivor Seager Smith was educated at the Newcastle School of Medicine of Durham University, and graduated M.B., B.S.Durh. in 1914. Shortly after the war broke out he obtained a commission in the Northumbrian Field Ambulance, R.A.M.C.(T.F.), in which he eventually held the rank of major. On his return home from Salonica in 1919, he went into general practice at Sunderland, where he soon became very popular. He leaves a widow and a young child.

The death is announced, by cable, of Dr. ARTHUR POOLE, of Umzinto, Natal. Dr. Poole graduated M.B., Ch.B. at Glasgow University in 1911, and held a commission in the R.A.M.C. from 1915 to 1919. After practising for a short time in Manchester he went to South Africa a year or two ago. He is survived by his widow, to whom he was married in 1921.

### The Services.

THE KING has conferred the Royal Naval Volunteer Reserve Officers' Decoration upon Surgeon Captain Arthur R. Bralley, M.C.

### DEATHS IN THE SERVICES.

Colonel Henry John Waller Barrow, Army Medical Service (retired), died at Weymouth on July 30th, aged 73. He was the son of Inspector-General T. W. Barrow, A.M.D., and was educated at Guy's. He took the M.R.C.S. and L.S.A. in 1871 and entered the army as assistant surgeon on September 30th, 1871; while the regimental medical system was still in force he served for a time in the 43rd Foot, now the 1st Battalion of the Oxford and Bucks Light Infantry. He attained the rank of colonel on September 25th, 1901, and retired on July 7th, 1910. He rejoined for service during the recent war, from December 24th, 1914, and was for some time in charge of a hospital at Epsom. In September, 1873, he served in medical charge of a company of the 43rd L.I., which attacked and destroyed a company of Moplah fanatics at Kolatara, on the Malabar coast of Southern India. Twelve years later he served in the Sudan expedition of 1885, at Suakin, and in the Sudan Frontier Force in 1885-86, when he was present at the action of Giniss, and received the Egyptian medal

and the Khedive's bronze star. Colonel Barrow's family have contributed several officers to the medical service of the army. His father, Inspector-General T. W. Barrow, served in the Crimea. His elder brother, Lieut.-Colonel T. S. Barrow, served in the A.M.D. from 1864 to 1884. His twin brother, Lieut.-Colonel F. E. Barrow, entered the same day as himself, but two places senior to him, served in Egypt, the Sudan, and South Africa, and retired in 1893. His son, Colonel H. P. W. Barrow, C.M.G., D.S.O., is now serving.

Dr. James Desmond McCarthy, C.M.G., late R.N., died at Sway, Hampshire, on July 28th, aged 84. He served as surgeon in the Royal Navy from 1872 to 1874, when he resigned in order to enter the Colonial Medical Service, in which he served for sixteen years on the West Coast of Africa. He was assistant colonial surgeon at Lagos from 1877 to 1880, and full surgeon from 1880 to 1884, when he became chief medical officer of the Gold Coast Colony. In 1891 he received the C.M.G. and retired in 1893. He served under Sir Garnet, afterwards Lord, Wolseley in the Ashanti expedition of 1873-74, and was present at the capture of Kumasi, being mentioned in dispatches and receiving the medal with a clasp.

### Universities and Colleges.

#### UNIVERSITY OF OXFORD.

At a congregation held on August 8th the degree of doctor of medicine (D.M.) was conferred upon M. O. Raven.

#### LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.

THE following awards of medical scholarships and exhibitions have been made on the results of the Board's examinations held in June:

University College.—Bucknill Scholarship: J. R. Pierre. Medical Exhibitions: A. S. Hatch, M. Levy.

Westminster Hospital Medical School.—Natural Science Scholarship: H. J. Shorvon.

London (Royal Free Hospital) School of Medicine for Women.—Mabel Sharman Crawford Scholarship: Marguerite M. Fenn. St. Dunstan's Medical Exhibition: Joyce R. Woods. Isabel Thorne Scholarship: Decima M. Tracey. Mrs. George M. Smith Scholarship: Kathleen E. Gambrell.

### Medical News.

THE formal opening of the winter session, 1923-24, of the Middlesex Hospital Medical School will take place on Tuesday, October 2nd. The introductory address will be delivered at 3 p.m. at the Scala Theatre by Mr. Somerville Hastings, F.R.C.S., on team work in nature. The prizes to successful students will then be distributed by H.R.H. Princess Alice, Countess of Athlone. The annual dinner will be held the same evening at 7.30 at the Trocadero Restaurant, with Sir John Bland-Sutton, F.R.C.S., in the chair.

THE movement known as Health Week was instituted in 1912, and in 1914, at the request of a meeting of local authorities, the Royal Sanitary Institute appointed a committee to undertake the central organization; but local celebrations in each centre are organized and controlled by local committees. The object of Health Week is to focus public attention for one week in the year on matters of health, and to arouse that sense of personal responsibility for health without which all public work, whether by the Government or local authorities, must fall far short of its aims. The next celebration will be held from October 7th to 13th.

ELSEWHERE in this issue (p. 292) is published an article on pure milk in which reference is made to the new tract on pasteurization published by the Ministry of Health. We are informed that a national milk conference will be held in the Guildhall, London, on November 21st. Papers are then to be read on every important aspect of pasteurization—methods and processes, physical changes, chemical changes, bacteriological changes, biochemical changes, and the financial and commercial aspect. The conference is being organized by the National Clean Milk Association, 3, Bedford Square, London, W.C.1.

THE address on "The adaptional machinery concerned in the evolution of man's body," delivered recently by Sir Arthur Keith as the twelfth Huxley Memorial Lecture, is published in full as a supplement to *Nature* of August 18th. The lecture by Professor N. Bohr on "The structure of the atom," published as a supplement in *Nature* of July 7th, is now obtainable separately at 6d., or by post at 7d.

IN his annual report for 1922 on the work of the South Travancore Medical Mission Dr. S. H. Pugh records that Mr. Howard Somervell, F.R.C.S., a member of the recent Mount Everest Expedition, has decided to join the staff of the institution.

Similar treatment in other cases has had an equally beneficial effect, although in some, where evidence of insufficiency of the digestive function of the pancreas was also found, I have proved it more or less difficult to deal with. I have had no personal experience of alkalosis in children, and, as far as I can find, there is little literature on the subject. It is probably that it is not one of the symptoms met with in pyroelectric encephalitis in infantile tetany, but accurate observations are apparently lacking. It is known, however, that many cases are induced in animals by injecting alkalis, and I am acquainted with one case where tetanic convulsions followed an attempt to treat a diabetic acidosis in an infant by intravenous injections of sodium bicarbonate. An interesting case of alkalosis, with periodic attacks of vomiting, in an adult has been described by Macleod and Gordon, who found that the condition could be controlled by large doses of dilute hydrochloric acid. Whether similar treatment might be useful in the cyclic vomiting of children is not certain until more is known about the acid-base equilibrium in that condition; but, as it has been found that alkalis have a beneficial effect in some cases, it is probable there is often an acidosis and not an alkalosis. Judging from the experimental work of Wilson<sup>1</sup> and

when no amoebae were found. No control bacteriological examination was made either, as the patient was too poor to pay for more than was absolutely necessary in order to guide treatment. No post-mortem examination could be made, but the symptoms very much resembled liver abscess. It would be interesting to know whether such a complication has ever been definitely found in an infection with this flagellate.

Chinosol was undoubtedly the only drug that seemed to have any good effect on this case. The creosote capsules were continued along with the chinosol and may have helped its action, but they seemed quite useless alone. Perhaps chinosol as an adjuvant in Dr. Whittingham's bismuth emetine treatment would improve his percentage of cures.

#### PILOCARPINE IN SUNSTROKE.

Dr. J. MCOSCAR (Buxton) writes: To be forewarned is to be forearmed. Having been a ship's surgeon and had several cases of sunstroke, I give you my experience of the worst case I once had in 1889.

The man, a steward, was told by me not to be on deck without a hat, as we were steaming in the tropics. However, one morning, having had a pint of stout, he was on deck without a cap; he fell down insensible, with stertorous breathing, pupils fixed and contracted, dry burning skin and quick pulse; his face, head, and neck were livid, and the carotid pulsations visible. I gave pilocarpine hypodermically, with one or two minims of croton oil, and placed him with loosened clothing in a cool place on deck. In a little while there was a reaction of the pupils and twitching of the eyelids. After six hours he became semi-conscious, but unable to move. The croton oil acted well; his body was rubbed all over every four hours with raw eggs and brandy. He gradually regained consciousness, and the next morning was able to take some milk food. After a week, during which he was closely watched, he returned to duty. Pilocarpine in these cases, with a good aperient, seems to be the radical cure. The captain, officers, and crew told me they had never seen such a bad case recover, having seen many. Probably pilocarpine had never been given.

#### DEATHS ASSIGNED TO PREGNANCY AND CHILDBIRTH.

BEFORE Parliament adjourned the Minister of Health, in response to a request by Mr. Rhys Davies, gave the following statistics affording all available information as to the comparative death rate of women assigned to pregnancy and childbirth in England and Wales and in various European countries:

|                        | 1913 | 1914 | 1915 | 1916 | 1917 | 1918 | 1919 | 1920 | 1921 | 1922 |
|------------------------|------|------|------|------|------|------|------|------|------|------|
| <b>Deaths in—</b>      |      |      |      |      |      |      |      |      |      |      |
| England and Wales*:    |      |      |      |      |      |      |      |      |      |      |
| per million living ... | 185  | 192  | 176  | 166  | 132  | 127  | 154  | 210  | 168  | 149  |

| Sweden:                |      |      |      |      |      |      |      |      |      |      |
| per million living ... | 53   | 58   | 63   | 56   | 51   | —    | —    | —    | —    | —    |
| per 1,000 births ...   | 2.28 | 2.60 | 2.90 | 2.66 | 2.46 | —    | —    | —    | —    | —    |

\* The deaths assigned to pregnancy or childbirth in England and Wales (per million living and per 1,000 births respectively) in preceding decades, commencing with 1861, were as follows:—1861-70: 341 and 4.70; 1871-80: 350 and 4.72; 1881-90: 318 and 4.73; 1891-1900: 301 and 5.09; 1901-10: 206 and 4.01. Prior to 1911 puerperal nephritis and albuminuria were not classed to pregnancy and childbirth, and consequently the rates shown from 1913 onwards are from 0.22 to 0.25 in excess of what they would have been under the old classification.

† The number of deaths per million living in Holland for 1911-15 (inclusive) was 126.

The number of deaths per million living in Denmark in 1920 was 60, and the number per 1,000 births was 2.55.

#### THE NEED OF RECONSIDERATION OF DIAGNOSIS IN CHRONIC CASES.

Dr. CHARLES J. HILL AITKEN (Kilnburst, near Rotherham) writes: A girl of 20 passed through an illness that, despite a tardy convalescence, was called acute bronchitis. Ten years later, considering herself to be of average health, she studied and took a diploma, qualifying herself thus to earn her living. As her health had deteriorated through her efforts, she rested for a year or two. Then, considering her health restored, she took a post offered her. Being enthusiastic and intelligent, her responsibilities were increased, as also her hours. At the age of 40 she was really a sick person, and for the first time in twenty years she was examined and pronounced phthisical. For ten years she lived a life of semi-invalidism, though reaping the reward of her care of herself, as she was better at 50 than she had been at 40. At this age (50) she resigned herself to a life of semi-invalidism. Then, by chance, on the Continent she consulted a medical man who, with a mind unbiased by her previous history, examined her systematically and decided to enucleate her tonsils, assuring her that she would benefit enormously by the operation. The tonsils were removed a year ago and found on section markedly

diseased. A little while back the patient, having enjoyed health to which she had for years been a stranger, was x-rayed, and, as the doctor who removed her tonsils expected, her lung was found to present the picture of cicatrization. What had happened was this. Three years ago or thereabouts the lung had healed, but as the symptoms to which the patient was accustomed continued she presumed she was still the victim of phthisis, and but for the reconsideration of her chronic case by a skilled medical man she would have continued her life of semi-invalidism, when only diseased tonsils lay between her and health. The late Professor John Chien used to say to his students, "Gentlemen, examine your patients." Someone equally well known, whose name I forget, used to say what amounted to "Gentlemen, re-examine your patients." I showed the above to the patient, and she remarked, "Yes. The moral for patients otherwise will be 'Change your doctor.'"

#### SERUM BY THE MOUTH.

Dr. R. A. PARKER (East Kew, Victoria, Australia) writes: With reference to the letter published in your issue of May 12th, 1923 (p. 840), I have had no experience of the oral administration of serum in the treatment of diphtheria, but my letter merely referred to prophylaxis. When a member of a household is affected with diphtheria, the oral administration of anti-diphtheria serum to the remainder of the inmates is an efficient and convenient form of prophylaxis, and the method raises no objections from the parents and children. The dose should be one to two thousand units. The important point is that the serum must be sipped slowly and retained under the tongue for a minute or more before it is swallowed.

#### THE BLOOD PRESSURE AFTER OPERATION.

Dr. A. LEHRNBECHER (Eberswalde, near Berlin) writes: In his letter published in the BRITISH MEDICAL JOURNAL of May 26th (p. 916) Dr. Edgar Cyriax refers to his investigations on blood pressure, with special regard to differences in the two arms in cases of unilateral conditions, and he states that my own results taken before, during, and after operations are very liable to lead one to wrong conclusions, inasmuch as the readings were taken indiscriminately from either arm. I regret that at the time of my investigations I was ignorant of Dr. Cyriax's publications, as owing to bad economic conditions in Germany the medical journals of other countries are unobtainable. I do not think, however, that this possible source of error has materially affected the value of my results, as it only comes into question when the readings are compared immediately before and immediately after the operation under different conditions—namely, the operating theatre or the ward. The readings during the actual operation and during the ensuing days are of much greater value from the point of view of prognosis, and in my series of cases these were always taken on the same side and under the same conditions. As the factors that influence blood pressure are as yet imperfectly understood, I consider it advisable for all future workers to avoid the source of error referred to by Dr. Cyriax, and to make it an invariable rule to take observations always from the same arm.

#### FLIES IN INDIA.

MOST of us are familiar with photographs, sketches, and diagrams illustrating the evil propensities of flies, but a little pamphlet issued by the Public Health Department of the United Provinces of India presents some novel features. It includes eighteen pen and ink sketches of Indian village life and the connexion of flies therewith, and the letterpress consists of a conversation between a villager distressed about his son and a doctor who tells him what he must do to avoid a recurrence of his trouble. Both text and pictures are the work of Mr. A. Sousa, F.R.C.S. Ed., who is Director of Epidemiology in the Province in question.

MESSRS. A. W. GAMAGE, LTD., inform us that they have purchased the entire stock of the Stalistic Tyre Company, and are offering the tyres, which consist of nearly every standard size, at prices much lower than the cost of manufacture.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 28, 29, 30, 31, 34, and 36 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 112.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

|                                                 | 2 s. | d.   |
|-------------------------------------------------|------|------|
| Six lines and under ...                         | 0    | 9 0  |
| Each additional line ...                        | 0    | 1 6  |
| Whole single column (three columns to page) ... | 7    | 10 0 |
| Half single column ...                          | 3    | 15 0 |
| Half page ...                                   | 10   | 0 0  |
| Whole page ...                                  | 20   | 0 0  |

An average line contains six words. All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded. Advertisements should be delivered, addressed to the Manager, 42, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference. Note.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

but the quantity is insufficient, the quality is mediocre, and the infant does not thrive.

At the recent conference to which I have referred above a strong plea was made for wet nurses, but as a rule an artificial substitute for the missing natural aliment has to be sought. Experience and the best medical judgment have commanded the use of cow's milk in some form or other as generally the best and most practical substitute for mother's milk. It is when we come to the form in which cow's milk is to be used we find ourselves on debatable ground.

Primarily there were two schools of thought, one of which advocated living instead of "dead" milk. The advocates of so-called "living" milk claimed that raw milk possessed diastatic activities or ferments which played an important physiological part in regard to the child. Certain of these ferments of a digestive order, they considered, assisted and completed the child's own digestive capabilities, whilst others were absorbed by the mucous membrane of the intestines and played an exciting part *vis-à-vis* the nutrition and cellular activity of the infant. This theory, seductive as it is, is unsupported by proof, and the employment of raw milk in the band-feeding of infants has not furnished us with the results anticipated by theorists. On the other hand, this method of feeding can produce very serious results by reason of the bacterial infection it can engender. Indeed, in the light of recent work dealing with the subject it has been established that, except in the case of human milk, the fact that milk is "living" constitutes a disadvantage rather than an advantage for the nourishment of the infant.

Professor Martian, the distinguished French pediatrician, is very fond of saying, "Cow's milk is better raw than cooked for calves and better cooked than raw for infants." When we consider the effects of heat on the constituents of milk we find that the chemists tell us that there is no demonstrable difference in the composition of various animal casings. "Of chemical science they are identical, but biology shows us that this conception is erroneous and that each species of animal possesses its own particular kind of casing, differing distinctly from the others in some special characteristic. It is the nature of this special characteristic that renders the casein of one animal to an appreciable extent toxic on ingestion by an animal of another species, and I suggest that it is this point which has hardly been fully appreciated in the past. Cow's milk is to a certain extent toxic to infants, and indeed to all animals except calves. We must start out with this fact in our minds in considering the use of cow's milk in infant feeding, and its appreciation once and for all disposes of any leanings towards raw milk, as heat has been found to be most efficacious in diminishing the special characteristics of an albumin. Heat causes an albumin to lose its individual characteristics and thereby neutralizes its toxic action. In the manufacture of therapeutic serums the products are submitted to a series of successive heatings, which diminish this toxic action. The French are so alive to this need for heating cow's milk in order to adapt it to infant feeding that M. Rousseau, the chemist at the Ecole de Puériculture at Paris, has invented an apparatus by which a thin film of milk is submitted to a high temperature for a short period in a steam jacket.

Despite the progress which has been made in improving the quantity and quality of cow's milk at reasonable cost, the public health official and the pediatrician in Europe, Asia, and America are confronted in many localities (a) with the high cost, (b) with the scarcity, (c) with the impossibility of securing a safe supply, and (d) with the inability of a large number of householders properly to handle and prepare milk in the home. In a report issued by the Treasury Department of the United States Government last October, Drs. Clark and Collins of the United States Public Health Services stated: "Over large areas of our country (America) milk is not produced in sufficient quantity to supply the local needs. One of the writers visited a State where in some localities milk retails at a dollar a gallon, obviously beyond the means of a large part of the population. In other sections of this country it is produced in such quantity that much of it goes to waste because of lack of transportation facilities or the limit of the distance which milk may be transported, the factors of time and the temperature of the milk being the limit of the distance which milk may be transported."

In a report issued by the Treasury Department of the United States Government last October, Drs. Clark and Collins of the United States Public Health Services stated: "Over large areas of our country (America) milk is not produced in sufficient quantity to supply the local needs. One of the writers visited a State where in some localities milk retails at a dollar a gallon, obviously beyond the means of a large part of the population. In other sections of this country it is produced in such quantity that much of it goes to waste because of lack of transportation facilities or the limit of the distance which milk may be transported, the factors of time and the temperature of the milk being the limit of the distance which milk may be transported."

operating to cause deterioration. It is for these reasons that inquiring minds have turned to the solution of these problems and sought to make generally available this valuable food at a reasonable cost by converting it into a form in which its bulk and perishable nature would be diminished. Two products have been the results of their labours—namely, (1) condensed and (2) dried milk."

The former of these products has been the subject of much controversy, and there have been battles royal between authorities on infant feeding in both Europe and America on the value of condensed milk; some writers have praised it to the skies, whereas others have damned it to the depths of perdition. Except for occasional use most physicians in both hemispheres were against the use of condensed milk until comparatively recently, when in January, 1919, Professor Calmette made a notable contribution to the Academy of Medicine in Paris. After recalling the terrible mortality which raged at Lille during the German occupation and describing the physiological misery of the inhabitants, the development of tuberculosis due to privations and insufficient nourishment, Calmette made an unexpected and surprising statement. He claimed that the decrease in the mortality of infants under one year of age was due to the fact that their exclusive diet was condensed milk supplied by the neutral Committee of Assistance.

"Experience," he said, "has demonstrated the quite remarkable excellence of this regimen, with the exclusive use of sweetened condensed milk our infant welfare centers, which have not ceased exercising their activities, have seen the disappearance of enteritis and the gastro-intestinal troubles to which, before the war, 18 to 21 per cent. of the Lille babies succumbed in the course of their first year."

The claim of such an authority as Calmette naturally received a great deal of attention, and his experiences in Lille have been followed up by other French workers. Dr. P. L. Tassabehere, director of the laboratory of the Faculty of Medicine, Paris, who has written a small treatise entitled *Le Lait Condensé*, which was awarded the Prix Jeunesse by the Faculty of Medicine in Paris in 1919. This has been translated into English under the auspices of the monthly review *La Médecine*. The author's view may be gathered from the following brief extract:

"When a mother cannot nourish her child herself the doctor will do well to recommend condensed milk. Feeding with condensed milk requires careful management, like all artificial feeding, but I assert when so managed it is suitable for children of any age, even from the first weeks after birth. Hundreds of observations have led me to this conviction, which I hold in spite of the opinion of those medical men who see in the good results obtained a mere chance success or an apparent one only." I am inclined to think that most British observers will be amongst the medical men so referred to, as personally I have found that infants reared on sweetened condensed milk are fat, pale, and often listless. The obvious fault in such dietary is the large amount of cane sugar, but this defect is glossed over by Dr. Tassabehere in the following words: "The small percentage of cane sugar in dilutions of condensed milk has been observed to do no harm, and even at its worst has nothing but a slight laxative effect if not digested. This is often desirable in infants with a tendency to constipation. The sour gases stools of carbohydrate indigestion are not due primarily to sugar but rather to the abnormal flora of the intestine causing putrefaction."

This statement I find most unconvincing, and I shall be surprised if this audience agrees with the French savant. It must not be supposed that Calmette's remarkable claims for condensed milk have been generally accepted by the medical profession on the other side of the Channel; on the contrary there is a large group of specialists who strongly support the use of the second form of preserved cow's milk to which I have referred. Drs. Artaud and Dorlencourt are just as enthusiastic with reference to dried milk, and I think I am right in saying that, on the whole, while the older pediatricians in Paris stick for fresh milk, the younger men advocate the dried variety. Milk powder is, indeed, only beginning to make headway, which is surprising, as the product was first suggested as a food for infants in France nearly twenty years ago. Personally I have been acquainted with milk powder for nearly fifteen years and have used it extensively in India. A great deal

## Surgery.

## 120. Tuberculous Disease of the Knee-joint.

M. AUVRAY (*Bull. et Mém. Soc. Chir. de Paris*, June 5th, 1923, p. 812) describes a method he has adopted with success in treating tuberculous disease of the knee-joint in children. The method is based on the opinion that tuberculosis shows a predilection for the epiphysis because of the poor blood supply in that region. He finds that by increasing the blood supply at this point the tissues are made as unfavourable as possible for the growth of the tubercle bacillus. He uses a series of bone grafts, some of which penetrate the bone down to the epiphysis, whilst others are placed subcutaneously outside these and supply the nourishment necessary for their vitality. A marked cellular reaction follows round the grafts, and the grafts themselves grow in length and breadth. The author demonstrates the success of this procedure in twenty cases, and he says that the results depend largely on the use of grafts of bone and periosteum from the patient's tibia, careful asepsis, and rapid transference of the graft to the bed already prepared for it. After the operation complete immobilization must be maintained. The graft is made to penetrate the diaphysis and epiphysis without entering the joint, and appears to act by increasing the circulation around it. It also produces a process of osteitis, and this condensation leads to destruction of the diseased tissue. In all the twenty cases the grafts have retained their vitality and the results, extending over five years, have been entirely satisfactory. In all cases the patients have some mobility of the joint, and in a number of them the mobility is practically complete.

## 121. Fractures of the Femur in Children.

C. G. BARDICK and I. E. SIRIS (*Annals of Surgery*, June, 1923 p. 736) find that fractures of the femur in children are almost invariably followed by a good functional result. A satisfactory anatomical reduction is not essential for perfect function. In many cases where shortening appeared on discharge from hospital within a year or two there was an appreciable lengthening. In children up to the age of 6 the treatment recommended is suspension in a Bryant frame. Both legs are suspended from the frame, the buttocks being kept two inches off the mattress. Adhesive plaster is applied from the top of the thigh, as the whole of the soft parts and the lower fragment will otherwise be pulled down. In older children the most satisfactory procedure is the plaster spica with continuous extension. After reducing the fragments with plaster traction straps the femur is maintained in moderate abduction by a plaster spica. The plaster is kept on for six weeks and exercises then instituted. The use of a Hodgen or Thomas splint is not advised except in compound fractures. An open reduction is rarely indicated, as skeletal traction will almost always correct any marked deformity. A certain number of cases, irrespective of the form of treatment, will be followed by a lengthening of the fractured side. The report is based on 268 cases of fractured femur, and emphasizes the conservative mode of treatment adopted by the authors.

## 122. Primary Carcinoma of the Ureter.

To the thirty-two cases of carcinoma of the ureter already recorded in the literature, LOUISE H. MEEKER and J. F. MCCARTHY (*Journ. Amer. Med. Assoc.*, July 14th, 1923, p. 104) add one more case. The origin and nature of the fatal illness was primary carcinoma of the right ureter. Secondary and terminal factors were generalized metastases to the liver, pericardium, lungs, spleen, pancreas, left kidney, lymph nodes, and skin. There was right hydronephrosis. Anatomical findings consisted of dense adhesions about the tumour, the right external iliac vessels were embedded in the tumour, and a polypoid nodule, 1 by 2 mm., was present in the bladder mucosa near the orifice of the right ureter. Concerning the histogenesis of this tumour, the evidence indicated that it had developed from the epithelium lining the ureter.

## Acute Osteomyelitis.

123. N. G. SUTTON (*Med. Journ. of Australia*, May 12th, 1923, p. 517) points out that acute osteomyelitis occurs most frequently in children and that the death rate is considerably over 10 per cent. The treatment is entirely surgical and should be insisted on as soon as a diagnosis is made. Bone destruction occurs early in the disease, and the only way of preventing it is by providing early drainage for the inflammatory products. The least radical operation advised is incision down to and including the periosteum. At the other extreme certain surgeons recommend that the whole

diaphysis should be resected subperiosteally. Ochsner and Crile advise splitting the periosteum and carefully opening the medullary cavity and making sure that free drainage is provided. The author maintains that in practice it is always wiser, even in milder cases, to open the bone. Even if no medullary pus is found little harm is done, whilst if a medullary focus has been neglected great harm may ensue. Having opened the bone free drainage should be provided and an antiseptic solution used to wash out the cavity. The mortality of the disease depends on the promptness of diagnosis and treatment and the efficiency of drainage at the primary operation.

## 124. Pyelography in Obscure Abdominal Symptoms.

R. F. O'NEIL (*Boston Med. and Surg. Journ.*, May 3rd, 1923, p. 671) points out that many cases of abdominal pain have their origin in the urinary tract and are not infrequently unassociated with urinary symptoms or any gross abnormality in the urine. Since the wider application of pyelography great advances have been made in the study of renal and ureteral pathology, and we have an extremely accurate method of diagnosing or excluding lesions of the urinary tract. Pain in the acute lesions, as in renal colic, may be a fruitful source of error when occurring in the right side, as the symptoms are often confused with appendicitis and gall-bladder lesions. Certain calculi are not demonstrable by x rays and symptomatically cannot be diagnosed from kinks and ureter strictures without having recourse to the ureterogram. It is frequently impossible to judge whether a tumour of the right upper quadrant of the abdomen is a distended gall bladder, cyst, or lesion of the kidney. In all such conditions the pyelogram is valuable. A 12½ per cent. solution of sodium iodide is used, which is non-irritating and non-toxic; the fluid is injected slowly by the gravity method and stopped when it causes discomfort. Where bilateral pyelograms are wanted it is better to inject each side at a different sitting. Much depends on the proper interpretation of the plates, and what appears to be an abnormal renal pelvis is often merely a defect in the injection of the fluid. Illustrative cases are described with radiograms. The author holds that pyelography is a very reliable diagnostic procedure and one which should be employed in all doubtful cases of abdominal tumour before resorting to exploratory operations.

## 125. Operative Treatment of Hydronephrosis.

A. CHALIER and M. VERGNORY (*Bull. et Mém. Soc. Chir. de Paris*, March 27th, 1923, p. 501) report the case of a large hydronephrosis in a child aged 13, caused by constriction of the ureter over an abnormal renal artery, and discuss the treatment of the condition. The renal condition in the case reported remained undiscovered for a considerable period, and, as so frequently happens in such cases, the symptoms were thought to be gastro-intestinal in origin. The abnormal artery was the cause of the hydronephrosis, as it formed a sharp band across the ureter. Above the vessel was the distended ureter, while immediately below the ureter was normal and even diminished in size. The condition found was such as to make a conservative operation impossible. Division of the vessel alone would have led to necrosis of the area of the kidney it supplied and have resulted inevitably in a secondary nephrectomy. With regard to the best means of approaching the kidney, the authors consider the anterior route has great advantages in large tumours of the kidney; it gives the best access to the kidney and its pedicle, and it also enables the organ to be delivered outside the wound more easily. Also, where there is no evidence of infection they consider the transperitoneal route better than the pararectal. It makes the separation of the colon easier and the investigation of the tumour is simple, while the peritoneal cavity can safely be packed off with swabs. Haemorrhage can be better controlled, and when the operation is completed the colon is simply restored to its position.

## 126. Fatality from a Local Anaesthetic (Albromin).

H. KAERN (*Ugeskrift for Læger*, May 24th, 1923, p. 379) points out that the claim is made for the local anaesthetic albromin that it is practically atoxic. In a 0.5 per cent. solution it is said to be as effective an anaesthetic as a 2 per cent. solution of novocain-suprarenin. Albromin is also said to keep better and to be less affected by boiling. The author has given this anaesthetic in several cases, and though the anaesthesia was satisfactory the drug was apt to cause severe cerebral symptoms reminiscent of cocaine poisoning. These symptoms were much less frequent and severe when adrenaline was added to the solution, but, in spite of this precaution, a strong man, aged 28, operated on for a swelling of one testicle, died a few minutes after 70 c.cm. of a 0.5 per cent. solution had been injected into the field of operation. The symptoms were violent headache, followed by convulsions, cyanosis, and loss of consciousness.

I do not propose to discuss details, but merely to refer to

a few salient points. A rubber bandage was always used

as a tourniquet, and the leg firmly held by an assistant across

the opposite leg. The advantage of this is that further

flexion and rotation can easily be obtained. The surgeon

stands on the opposite side and is thus enabled to look

directly into the joint. This series of cases only includes

those in which a definite diagnosis of displaced cartilage had

been made, therefore Anandale's transverse intercartilag-

incision was used, modified by a slight curvature upwards

extended to half-way round the joint, the internal lateral

ligament not being endangered, as this structure lies

postero-internal. I am aware that the vertical curved

incision of Sir Robert Jones gives a better exposure for a

general survey of the joint, but when the diagnosis of dis-

placed cartilage is practically certain the transverse incision

gives a more direct approach.

The cartilage, having been exposed, is hooked out and as

much as possible removed, the synovial membrane then

being inspected for fringes, tags, etc. Sutures of plain

cattgut are used for synovial membrane and capsule, and

silkworm gut for the skin, the sutures being interrupted so

that any excess of post-operative effusion can escape between

the stitches. A bandage is applied firmly before the tourni-

quet is removed, and the patient returned to bed without a

loosen the bandage as swelling of the joint renders it

uncomfortable.

Probably no muscle in the body wastes more rapidly than

the quadriceps extensor, and therefore massage of the

muscle is commenced on the second day. At the end of four

days the bandage is further loosened to allow limited move-

ment, which is speedily encouraged, and the patient is

allowed up with a stick at the end of twelve to fourteen

days, the inner border of the boot being raised about a third

of an inch to take the strain off the inner aspect of the

capsule.

In this series of fifty cases on only one occasion was the

external cartilage the seat of the trouble. Von Bergmann

states that the internal cartilage is separated "more than

twice as commonly as the external";<sup>2</sup> this probably under-

minates the relative frequency of pathological

changes found in this series; in many cases more than one

indicated the most obvious lesion.

Circumferential split

Dense abnormal mobility

Flexed or flattened

Doubtful increased mobility

27

15

6

2

Although in the last group no definite mobility was dis-

covered, removal of the cartilage relieved all symptoms—a

condition which has been remarked upon by Kendle Short.<sup>3</sup>

With regard to the length of time which should elapse

between separation of the cartilage and operation, it is wise

to wait a few days until the acute traumatic inflammatory

reaction has subsided. There seems no need to wait until

all the fluid has been absorbed; this may be a matter of

weeks. In seven cases an ounce or more fluid escaped on

opening the joint and no untoward complications occurred.

# PROGNOSIS.

In considering the prognosis special attention was paid

to the following features:

(a) Recurrence.

(b) Pain.—This is, of course, a difficult symptom to assess

at true value. Many patients complain of slight or

diminishing pain for an interval varying from a few weeks

to two years, but unless it caused actual disability such pain

has been ignored in considering the prognosis.

(c) Movement.—With a relatively healthy joint, followed

by absence of splinting and early movements, there seems

to be no reason why movement should be restricted after

operation.

(d) Stability.—A "feeling of weakness" is a common

immediate after-effect of meniscectomy. This is in a great

measure psychical, as the patient is often accustomed to the

operation.

There was one recurrence in each of the three groups.

Results fall naturally into three groups:

1. Good.—Where there is negligible pain, no sensation of

weakness, and movements are unimpeded. This group

includes two professional footballers and one music-hall

dancer, all of whom subsequently followed their normal

occupation.

2. Fair.—This includes cases in which there is slight

limitation of movement or pain occurring periodically or

when the limb is placed in certain positions.

3. Poor.—This includes cases in which recurrence takes

place or range of movement is less than a right angle. Also

are included cases in which pain is frequent or a sensation

of weakness remains in the joint.

In considering these cases it is interesting to note that

prognosis appears to depend chiefly upon two factors—

firstly, the number of attacks, and secondly, the age of the

patient. Hence I have analysed the series from these

standpoints.

A. Prognosis in Relation to Number of Attacks.

(Group I consists of cases with not more than three attacks; Group II

of cases with more than three attacks.)

There were no recurrences in Group I; two in Group II.

It will be noticed that, as would naturally be expected,

the results of operation before repeated attacks have caused

stretching of the supporting structures or early osteo-

arthritides are much superior to those obtained in later cases.

In one this

failure was due to excessive traction on the cartilage during

removal causing separation of the posterior remaining por-

tion—a danger which has been emphasized by Sir Robert

Jones.<sup>4</sup>

The occasional pain relatively more frequent in the later

cases was usually associated with changes in the weather,

suggesting its association with secondary osteo-arthritis.

B. Prognosis in Relation to Age.

(Group III consists of cases under 30 years of age; Group IV of cases

aged 30 and over.)

Group III

Group IV

Pain:

None or insignificant

Periodic

With certain movements

Unimpeded

Slightly impaired

Less than 90 degrees

Stability:

Normal

Sensation of weakness

Results:

Good

Fair

Poor

## 433. Idiopathic Dilatation of the Colon.

D. FIRTH and K. PLAYFAIR (*Arch. of Radiol. and Electrother.*, April, 1923, p. 321) point out that all cases of megacolon are not necessarily cases of congenital idiopathic dilatation, since enlargement of the rectum and colon may arise secondarily to mechanical obstruction low down from such causes as stricture. Hirschsprung's disease is a dilatation and hypertrophy of the large bowel due to an obscure cause, but apparently congenital in origin. The following hypotheses, among others, have been advanced to explain its origin—mechanical due to torsion or kinking, atresia of the rectum, and valve formation. Inflammatory changes seen in the gut are probably secondary in origin. A congenital origin (as was suggested by Hirschsprung), with a primary hypertrophy and a secondary dilatation, is supported by the early age of onset and may be allied to the congenital hypertrophic pyloric stenosis of infants. A case is recorded by the authors and a series of radiograms is given illustrating the condition; the gradual filling of the dilated intestine is well demonstrated. In the reported case there was also a scoliosis due to a congenital maldevelopment of half a vertebra, and it is interesting to note that it is said that congenital defects of the central nervous system are frequently associated with deformation of the skeletal system.

## Radiology and Electrology.

## 134. The X-ray Diagnosis of Pulmonary Tuberculosis.

J. TILLMAN (*Hygiea*, June 15th, 1923, p. 457) has compared the findings of ordinary physical examination with those of the x-rays in 300 cases of pulmonary tuberculosis in adults treated at a sanatorium in Sweden. In 25 per cent. the stethoscopic and x-ray examinations agreed approximately, and in 12.7 per cent. the x-rays showed signs of disease, whereas the stethoscopic findings were negative or doubtful. In 28.3 per cent. the x-rays showed more extensive disease than did the stethoscope, and in 30 per cent. the x-rays showed more intense or severe disease than did the stethoscope. There were only 2 cases in which the x-ray evidence was negative, although tubercle bacilli were present in the sputum, and there was only 1 case in which the stethoscopic evidence was positive and the x-ray evidence negative. Only in 6 cases were the findings of the stethoscope demonstrably superior to those of the x-rays, and the author concludes that the x-rays give much more complete information as to the presence, extent, and severity of pulmonary tuberculosis than does the ordinary physical examination. On the other hand, he regards the x-rays as an auxiliary to, and not a substitute for, other diagnostic tests. The comparison between the two methods was made in more or less unselected, consecutive cases, but all the technically faulty skiagrams were rejected, as well as those which could not be definitely interpreted as showing the presence or absence of tuberculous changes.

## 135. Skiagraphy of the Pubic Arch during Pregnancy.

CHASSARD and LAPINE (*Journ. de Radiologie et d'Électrologie*, March, 1923, p. 113) eulogize Fabre's method of examination of the pelvic inlet by pelvimetric skiagraphy. At the request of Professor Commandeur the authors have sought to apply the same method to the study of the pelvic outlet, and more particularly of the pubic arch. Clinically, the determination of its form is difficult. Measurement of the bi-ischiatic diameter does not indicate its height, shape, nor the opening of the subpubic angle. The authors describe their experiments with the "dry" pelvis, which led them to select the following position for the patient. In order to bring the pubic arch as closely as possible to the plate, the patient is placed astride of a narrow bench, with thighs abducted, the body leaning forward in order to place the pubic arch in position parallel to the plane of the plate. It will then be seen that the symphysis and the ischia are closely applied to the plate. Comparisons of plates thus obtained with skiagrams of the "dry" pelvis showed that, without absolute precision, they approximate very closely to the actual position. The patient's sacrum is inclined at (approximately) 45 degrees and the tube is directed vertically downwards; the tube selected should be hard enough (7° Benoist at least). It is indispensable that a reinforcing screen should be used, or, even better, a film with a double screen. The use of a localizing cylinder has been recommended also. The authors found that, in normal pelvises, the subpubic angle ranged from 103 to 68 degrees, the average being 83 degrees. The bi-ischiatic diameter ranged from 124 to 93 mm., with a mean 109 mm. This corresponds very closely to the classic measurements of Baudelocque, Farabeuf, and other obstetricians. The authors conclude that radiography following a definite technique permits

accurate estimation of all details of the pelvic outlet. The consider that this method of determining the obstetric bi-ischiatic diameter is more accurate than those usually employed, and that it should be used whenever there is suspicion of possible deformity.

## 136. Radiotherapy in Sarcoma of the Recto-Genital Septum.

L. SZAMEK (*Zentralbl. f. Gynäk.*, May 12th, 1923, p. 752) describes a case of a diffuse, rapidly growing sarcoma of the connective tissue of the recto-vaginal septum, which was treated with radium and x-rays with great success. When treatment was first instituted the tumour was large and infiltrating in all directions, but now, a year after treatment there only remains a little cicatricial thickening. Stimulated by his experience the author has collected statistics regarding sarcomata in this situation, and notes that operation or such cases is very unsatisfactory, the prognosis, as one would expect, being very much worse in the diffuse, but better in the hard circumscribed growths. Of 59 cases collected from the literature, the primary mortality was extremely high, being 30.5 per cent.; 37.2 per cent. developed recurrences or metastases soon after operation; only 32.2 per cent. left the hospital well, and as these were lost sight of the duration of the so-called cure cannot be discovered. Radiotherapy in the treatment of such cases seems to hold out great hopes, and, though statistics are rare yet, they are sufficient to show that radiation may cure where operation must fail; this is especially the case in the diffuse type, where the radical operation is so extensive that it is impossible to remove the whole tumour. The circumscribed variety are often mistaken for fibroids, etc., and their true nature is not discovered until sections are made after operation, and thus no statistics regarding radiotherapy for this type can be found. The author asserts that operation should not be performed first in cases which are to be treated later by radiotherapy, as operation opens lymph channels and blood vessels and allows sarcoma cells to enter the general circulation and produce metastases, radiotherapy being then of no use. As regards treatment, both radium and x-rays are advised, and the author suggests that if possible the radium should be placed within the tumour tissue to be sure of the best results. From the literature it would appear that all sarcomata, whatever their nature, are benefited and often cured by radiotherapy, authorities differing, however, in its efficacy for different types.

## 137. Radiograms of the Foetal Skeleton as a Sign of Pregnancy.

F. STEIN and A. ARENS (*Journ. Amer. Med. Assoc.*, July 7th, 1923, p. 4) assert that in the second half of pregnancy foetal radiograms are of definite confirmative value, and they give some interesting illustrations of radiograms showing the foetus in utero. In recognizing clinically obscure presentations and positions, and in differential diagnosis between pregnancy and other abdominal enlargements, the x-ray evidence is a deciding factor. By the employment of pneumoperitoneum the gravid uterus can be quite clearly shown on the radiogram in the early months of pregnancy, and the value of this in differential diagnosis is obvious. The demonstration of the foetal skeleton by x-rays is, say the authors, the most positive sign of pregnancy obtainable before quickening.

## 138. Physical Principles in Irradiation of Cancer of the Uterus.

ACCORDING to R. COLIETZ (*Journ. de Radiologie et d'Électrologie*, May, 1923, p. 201), there is abundant evidence—both experimental and clinical, in connexion with cancer of the breast and uterus—that both radium and x-ray applications in small doses exercise a stimulating effect on malignant neoplasms. In radiotherapy it is therefore of paramount importance to avoid radio-excitation of tumour cells such as may follow (1) too short exposures or (2) incorrect calculation of the dosage of x-rays or radium emanation received by deeply situated tumours or their metastases. In contrasting the usefulness of x-ray and radium treatment, there is an increasing amount of evidence of a specific superiority of the gamma rays of the latter, as regards capacity for destruction of the neoplastic cell. The author, in advocating a combination of x-ray and radium therapy, points out that to give x-ray treatment alone is to deprive the patient of the action of the highly specific gamma rays of radium; on the other hand, to give radium treatment alone is to neglect the superior penetrating powers of large-field x-radiations and a risk producing radio-excitation in deep metastatic foci. A detailed account is given of the application of these principles to the technique of irradiation in cancer of the cervix uteri.

# Memoranda

## Reviews.

### THE COMMON NEUROSES.

Dr. Ross is to be congratulated on having produced in his book on *The Common Neuroses* a volume handy in size and essentially readable in style, wherein the practitioner may find a useful guide to the treatment of many of his patients. Here are no abstruse discussions of psychological theories, no bewildering confusion of psychological terminology, but a plain statement of experience which anyone can understand. After an informing introductory chapter psychological views as to the etiology of the neuroses are briefly and simply discussed. Stress is rightly laid on the function drawn between the neuroses and the psychoses. A simple, and therefore acceptable, classification is given into neurasthenia, hysteria, and the compulsive neuroses. The symptoms and diagnosis of neurasthenia are next considered in two chapters, which are short but full of wise observation, and fruitful in practical deductions. The general treatment and the treatment of special symptoms there is nothing here which is not within the competence of any general practitioner to carry out, given only the necessary time and patience. The Freudian method is discussed, and while the author pays a deserved tribute to Freud for his pioneer work on the dangers of the method of psycho-analysis and its possible therapeutic shortcomings are pointed out. It is especially interesting to note the importance attached by the author to the value of work, and he is equally right in dismissing as a grossly exaggerated factor the excuse of overwork as a cause of the neuroses.

The author's treatment of the subject of hysteria is practical and the negativism of the hysteric is emphasized. We are interested to note that he is no believer in the reflex paralysis of Babinski and Froment, of which so much was heard during the war; this does he confirm the suspicions with which this doctrine was received by many, who, however, hardly felt equal to contradicting authorities so eminent. Dr. Ross favours the removal of the somatic symptoms of hysteria, such as paralysis, by direct suggestion coupled with explanation, and wisely insists on the importance of the physician being in a position to devote enough time to his first sitting. This treatment is, however, preliminary to the treatment of the underlying mental state, a matter of greater difficulty.

The book as a whole may be commended as a sane and balanced exposition of the views of one of wide experience. No doubt it will not find favour with those whose ideas are firmly set in one or other special psychological groove, but the student may learn a great deal from its pages and be grateful to Dr. Ross for clarifying much that has been made obscure. There are scattered throughout the book such *obiter dicta* as "Beware of praise from the hysteric," which add to the interest of the text and impress its lessons on the reader.

### A TEXTBOOK OF MIDWIFERY.

Dr. Fitzgibbon has followed the example of his two immediate predecessors in the Masterly of the Rotunda Hospital in publishing a book on midwifery. As the name, *Practical Midwifery*, indicates, he deals mainly with the practical aspects of the subject. Had he done so exclusively the book might have been more useful to the class of readers it addresses; his descriptions of the early ovum and placenta are so abbreviated that one not already familiar with the subject may find it very difficult to follow. Dr. Fitzgibbon deals very fully and elaborately with the whole subject of normal pregnancy and labour. In his introduction he states: "Ninety per cent. of cases will be found to be normal, and interference will result in the introduction of the subject may find it very difficult to follow."

greatest at the commencement of life, and becomes less as development proceeds. The rate of fall in the ratio is greatest in those animals with the shortest foetal life. It is pointed out that these general laws suggest many interesting applications. The rate of growth of cells is apparently determined largely by the ratio between the mass of the nucleus and the mass of the cytoplasm, and any thing which increases this ratio should act as a stimulant to cell growth. Starvation is the most obvious way in which this ratio can be increased, and starvation appears to stimulate cell growth as an after-effect, for if the growth of an animal is temporarily interrupted by starvation, growth is accelerated when feeding is resumed, and the animal temporarily starved may finally outstrip control animals. Finally, there appears to be a possibility that research along these lines may throw some light upon the causation of the abnormal growth occurring in malignant tissues. The possible applications of the method described are, of course, matters of speculation, but the writers appear to have rendered an important service by obtaining a basic series of facts which should serve as the foundation to many interesting studies upon the nature of the process of growth.

#### BRAIN ABSCESS.

Dr. Egleston's book on *Brain Abscess* is a record of personal experience in thirty-one cases, but he has also studied and analysed the clinical and statistical records of 125 cases of cerebral and 135 cases of frontal lobe abscesses. From this combination of material the treatment of brain abscess has been considered; considerations based on surgical pathology have served as the guide to much of the surgical treatment.

Chapter II deals with the general surgical technique of intracranial operations, but we are frankly disappointed with the information it conveys. In such a highly specialized monograph as this is intended to be, details of technique are expected, but the subject is dismissed in a somewhat curt fashion. For example, the directions for ventricular puncture are altogether inadequate. The chapters which deal with surgical pathology are more helpful. The author has adopted a terminology which as yet is unrecognized by other authorities. Depending upon the mode of entry into the brain of the different infections which cause brain abscess, he uses the terms "adjacent" or "secondary," and "intermittent" or "tertiary." This nomenclature seems unnecessarily complicated and the terms do not appear to us etymologically correct. Perhaps the most interesting part of the volume is the author's argument that from certain definite points of extracerebral origin cerebral abscess will occur in correspondingly definite cranial sites. So much does this view influence him that he believes the principle to be one of great importance in diagnosis. The diagnosis of the location of the abscess is described from the standpoint of where the intracranial pathological process will be with a given mode of entry rather than from that of the presence or absence of neurological symptoms produced by the lesion. This teaching has dangerous elements, and it is unlikely that it will receive the blessing of neurologists. The volume is really the record of the experience of a surgeon who has done his best to recognize and to treat the different problems of intracerebral suppuration; as such it will repay careful perusal, but it is not to be accepted as expressing the considered opinion of the majority of surgical observers. The addition of some anatomical illustrations would have materially enhanced the value of the book.

#### ANASTHESIA.

It is his handy little monograph, *Practical Anaesthetics*, Dr. CHARLES F. HARRIS has as his object, "to give to the medical and dental student and practitioner the theoretical and practical information sufficient to enable him to give

*Brain Abscess*, H. Egleston, M.D. New York: The Macmillan Co. 1932. (Kied. 8vo. pp. xix + 227; 40 figures, 31s. 6d. net.)  
*Practical Anaesthetics for the Student and General Practitioner*, By Charles F. Harris, M.B.E., M.A., M.D. Cambridge: Balliere, Tindall, and Cox, 1933. (Demy 8vo. pp. x+244; 22 figures, 7s. 6d. net.)

anaesthetics for all usual operations." He begins with a short chapter on the history of anaesthetics and then deals with such matters as vomiting, delayed chloroform poisoning, examination, and after-treatment. Next he describes signs and stages of anaesthetics, alkaloids used preparatory to induction, the airway and automatic respiration. Chapters follow on nitrous oxide, nitrous oxide with air or oxygen, and nitrous oxide in minor and major surgery. Attention is then directed to ether, Chloroform, and mitigated ether, open ether, ethane, warm ether vapor, and rectal, endotracheal, and intravenous ether. Passing next to chloroform, its physiological action, the Vernon-Harcourt inhaler, open methods, and the Junker inhaler are described in turn. A chapter follows on A.C.E. and similar mixtures, and is succeeded by others on ethyl chloride, spinal anaesthetics, anaesthesia in children, and on some special operations and diseases. The work is brought to a close by a chapter on anaesthetic accidents, emergencies, and shock. Careful perusal of the volume brings us to the conclusion that the author has succeeded in the task he set himself. While, of necessity, somewhat dogmatic in his statements, as is but natural in a short textbook on a by no means simple subject, his teaching is sound and his exposition clear and interesting. He has not made the mistake of overloading his text with many illustrations of complicated apparatus, and in the few cases in which apparatus is figured the descriptions are simple, those seeking fuller information being referred to appropriate monographs. The printers have done their part of the work well, paper, type, and binding being all that could be desired. The book can be confidently recommended to the student and general practitioner in search of a brief, sound, unbiased exposition of current practice in the art of anaesthesia, not involving the use of complicated and expensive apparatus.

#### A FRENCH CYCLOPAEDIA.

The fifth of the twenty-two volumes of Hocquard, Wiat, and Tisserand's *Nouveau Traité de Médecine* is divided into two portions, the first of which deals with the infectious and parasitic affections, almost entirely tropical, left over from the previous instalment. The first two articles, on chancre and ulcerating granuloma of the pudenda, are contributed by Dr. R. Demanche, who gives due credit for the original description of the latter disease to Conner and Daniels twenty-six years ago, and refers to the recent therapeutic use of emetine for its cure. Gonnard, first described by the late Professor Alexander Macalister of Cambridge under the title of "The horrid men of Africa," is discussed by Dr. Joyeux, who leaves open its relation to yaws, also summarized by him in the next article. Drs. Nicolle and Blazot, of the Pasteur Institute of Tunis, write on relapsing and tick fever, and Dr. Thibaut on sodoku, more familiarly known as rat-bite fever. Malaria occupies a hundred pages, containing many charts, in some of which illustrations of the form of the parasites present at the various phases of the paroxysms are reproduced at the bottom of the graph, thus bringing out the parallel evolution of the parasites and of the temperature. This important article and that on haemoglobinuric fever have apparently been contributed by Drs. H. Vincent and J. Hieune of the French Army. Among the articles on the parasitic diseases attention may be called to those on hydatids and cysticercus by Dr. F. Dêre of Rouen, who has so specially devoted himself to the subjects. Professor E. Brumpt's descriptions of human trypanosomiasis and bilharzias are illustrated by a number of original figures. The second and considerably the larger part of this work is devoted to an authoritative account of malignant diseases in all its aspects by Professor Gustave Roussy, who is so widely known as an expert neurologist, and Dr. Marcic Wolff of Paris. This is indeed a most valuable monograph, combining a critical survey of our knowledge with the

*Nouveau Traité de Médecine*, published under the direction of Prof. Tisserand, G. H. Hocquard, Fernand Wiat, and P. J. Tisserand, Secrétaire de la Rédaction, L. Garmier, Rasclouin V. Maladies infectieuses et parasitaires (No. 5). Le Cancer, Paris: Masson et Cie, 1932. (Roy. 8vo. pp. viii + 734; 35 figures, 4 coloured plates, Fr. 60.)

Bordier speaks highly of the value of diathermy for the treatment of cold paralysed limbs in anterior poliomyelitis. It is a valuable aid to electrical treatment, and the antagonists to the latter could not rationally object to it. The recovery from paralysis is greatly delayed by cold, and no method of heating is so effective as diathermy. I noted considerable improvement in the one case which I treated by diathermy for a period of three weeks. The treatment by diathermy of anterior poliomyelitis, in which the limbs are cold, is well worth full investigation.

Diathermy is, in my experience, most valuable in the treatment of the pain and spasms accompanying haemorrhoids. A case has recently been under my care at St. Bartholomew's Hospital. The patient complained of pain, bleeding, and the "coming down" of piles during defaecation, which he had to replace afterwards. After a course of diathermy, applied by means of a rectal electrode, the pain and bleeding disappeared. He said that something came down during defaecation, but only to a slight degree. He was examined by a surgeon with the proctoscope, but no haemorrhoids could be seen. If new fibrous tissue has formed in the pile it cannot be expected that diathermy will make it disappear, but the pain and discomfort can, in my experience, be permanently relieved.

Diathermy should be an efficient method of treatment of dysmenorrhoea by reason of its power to relieve congestion and painful spasmodic contraction. It is recommended by Bordier, and I believe that Dr. Turrell has obtained good results. The question of technique is one of importance. Bordier treated one case by placing one electrode in the vagina so that the metal end made contact with the cervix, the other being placed on the hypogastrium. By this method the uterus would receive a greater share of the diathermy than would be the case if both electrodes were placed on the skin, the vaginal electrode replaced by one on the buttocks or sacrum.

Diathermy should also be given a trial in cases of chronic para- and peri-metritis. I treated one case of parametritis before the war, and the patient derived some relief from pain, but did not continue the treatment.

A malady which is frequently seen in hospital electrical departments is coccygodynia. I see that Bordier, in his book, recommends diathermy for this condition. In my hands this treatment has not been very satisfactory.

Diathermy has been tried by a few workers in the United States and Germany for pulmonary tuberculosis. It has been said that in some cases the night-sweats had ceased, the temperature was lowered, and that the patients felt better and gained weight. If diathermy possesses therapeutic action in pulmonary tuberculosis the benefit derived is likely to be due to the increase of blood and lymph supply to the affected parts, and perhaps to the increased secretion of mucus, not to a direct germicidal action, because a temperature high enough for this purpose cannot be safely produced in the lungs. Nagelschmidt says that early cases only should be treated; if more advanced cases are treated there is a risk of increasing the haemoptysis.

I have refrained from speaking on the use of diathermy for the treatment of hypothermia, local and general, of neuritis, and of high blood pressure. Its value has been sufficiently established in these diseases.

In the subsequent discussion I trust that we shall hear the experience of others in the treatment not only of the diseases which I have mentioned, but also of others. Diathermy has established its position in therapeutics; it can cure or relieve some diseases for which other measures are unsuccessful. In other diseases in which simpler therapeutic methods are often successful diathermy has procured success in cases that resisted treatment.

the inception of the investigation by him before the war. It was taken up again after the armistice, and it is since then that I have been associated with it. All the earlier work and most of the later has been done in the Electrical Department of St. Bartholomew's Hospital, presided over by Dr. Cumberbatch.

In January, 1922, we made a communication to the Electro-Therapeutic Section of the Royal Society of Medicine, giving the results of treatments up to that time. Treatment of gonorrhoeal infection of the urethra in the male was undertaken last of all the regions on account of the fact that the work was started as an investigation into the treatment of gonorrhoeal rheumatism. It was natural, therefore, that cervicitis and urethritis in women and prostatitis in men should first receive attention after the joint affections.

The diathermy current was chosen because of the vulnerability of the gonococcus to heat and because by this means we can raise the temperature of the tissues concerned.

Growth of the gonococcus takes place in culture between 77° and 100.4° F. The optimum temperature for its growth is from 95° to 98.6° F. Exposure to 109° F. for seventy-six minutes, or to 111.2° F. for fifty-four minutes, or to 113° F. for thirty-seven minutes kills the organism. It is clear, then, that the gonococcus is less resistant to rises of temperature than most of the pathogenic organisms.

The foregoing observations, however, only apply to cultivations, and the temperature which is most suitable to its growth in living tissues is not known. Nor do we know the temperature to which it is necessary to heat it in order to kill it in these circumstances.

From the results of repeated observations it is clear that in the treatment of gonorrhoea by diathermy the effect produced is not due to the direct effects of heat alone. Gonorrhoea affecting the female urethra and cervix may be rapidly abolished, yet I have never been able to satisfy myself that the female urethra or cervix is heated above 112° F. during these treatments, and it is not necessary to heat it to this degree for longer than ten minutes. On the other hand, we have frequently heated the first two inches of the male urethra to this temperature for longer times without effect on the course of the disease.

From the results of observations on the effects of heat on cultures it follows that the two factors, temperature and time, must be taken into account in considering the direct lethal effect of heat. In living tissues there are the indirect effects of heat also to be considered. These indirect effects may be due to the effects of heat upon blood, upon the vessels, upon the mucus-producing cells, and upon other cellular activities. Indirect effects of heat may be present in laboratory experiments from chemical changes taking place in the culture medium on account of the heat, but it is doubtful if this will be so at the temperatures attained in these circumstances. If the indirect effects are absent it would account for the higher temperature and the greater time required to destroy under these conditions.

The fundamental results of raising the temperature of living tissues are not known. There are two factors to be considered—namely, the temperature attained and the time of the application. In dealing with living tissues the element of time is not so important as in the case of its application to cultures, because in the former reactions affecting blood and blood supply and other tissue reactions are set up after a short application and continue for some time afterwards. It is for this reason that a treatment lasting ten minutes or so may be as effective as one lasting half an hour.

Gonococcal infections of joints, of the cervix and urethra in females, and of the prostate and epididymis in males, are amenable to diathermy treatment because by this means these parts can be heated to a temperature which for these parts in these situations is lethal within the time of a treatment, when to the direct effect is added the secondary effects of heat and because this temperature is below that producing pain or destruction of the tissues concerned. In considering the temperature-time product in regard to the secondary effects of heat there is a minimum temperature which must be attained in order to get these effects and also a maximum beyond which they are again

Clinical Assistant, Electrical Department, St. Bartholomew's Hospital

#### THE TREATMENT OF GONORRHOEAL AFFECTIONS BY DIATHERMY CURRENTS.

THE following is a brief account of some work which has been carried out on the treatment of gonorrhoeal affections by diathermy currents. Dr. Cumberbatch has mentioned

LONDON'S WATER SUPPLY.

The Metropolitan Water Board's seventeenth annual report, by Sir Alexander Houston, for the year ending March 31st, 1923, is notable for its full introduction, in which a vivid and most interesting account is given of the whole water scheme of the metropolis. The story is clearly a labour of love on the part of its author, who sedulously avoids technicalities of language which might repel a reader without scientific knowledge. It is intended for "people of all classes," who "are now taking a real interest in water and are wanting to know much more than previously of rainfall, sources of supply, methods of purification, and means of distribution."

The supply is for nearly seven million persons, covering over 537 square miles in six administrative counties. Four-fifths of the water is drawn from polluted rivers, and yet London is one of the healthiest cities in the world. The three-fifths come from the Thames, one-fifth from the Lee, and one-fifth from deep wells. It is distributed by 6,577 miles of pipes, and over 45,000 horse-power is needed for its collection and distribution.

Deep Wells.

Deep wells are the purest source, situated in Kent and the Lee valley, and though the water is hard the bulk of it needs no treatment. Three of the wells, however, are so situated or contain such chemicals in solution as to require filtration or chlorination or both. Deep well water is clear, sparkling, and pleasant to drink, with few bacteria or microbes of any sort, and its hardness is not regarded as harmful. Of the (in round numbers) 40 million gallons daily from deep wells in Kent and the Lee valley, 10 millions are not supplied directly, but are pumped into the Lee or New River, and pass through their filters. Sir Alexander Houston says that the supply from the deep wells, even omitting what is pumped into the Lee, would suffice to supply Birmingham at the rate of 35 gallons per head per day. That is a kind of illustration he is fond of as a convenient measure of the greatness of the scheme.

River Sources.

The Water Board is not the conservancy authority, and so has no control over pollution of the Thames and the Lee. Its functions begin with the intakes. The Thames, though polluted, is partly or largely self-purifying, and in summer, when the level is low, many sources of pollution fail to reach it above the intakes.

The New River is a diversion of the waters of the Upper Lee into an artificial channel nearly thirty miles long. It is the purest of the river sources, but the storage reservoirs are small and the filtration area limited, so that up to a few years ago the winter floods used to cause deterioration of the supply, and chlorination before filtration often gave the water an appreciable chlorine taste. Difficulties, however, are now being overcome, and the only remaining trouble is vegetable growths, which in warm spring weather may interfere with the flow and block the sand filters, so that rapid mechanical filters are now being experimented with. In fact, during the whole year now a high standard of purity is reached. The New River itself would suffice to supply the water needs of Liverpool or Manchester at 35 gallons a head per diem.

The River Lee.—Isaak Walton's river is not too pure, but the reservoirs, which in total area amount to lakes, purify by sedimentation, and there is also slow sand filtration. The Lee yields over 50 million gallons a day, and would meet the needs of both Sheffield and Bristol at 35 gallons a head per diem.

The Thames.—This great river provides about 150 million gallons per day, and at the 35-gallon standard would supply half a dozen great cities—Glasgow, Birmingham, Manchester, Liverpool, Sheffield, and Bradford. The water is excepting in floods. The reservoir capacity is over 7,000 million gallons, and is being doubled. Before the war 70 to 100 million gallons, and is being doubled.

London: J. S. King and Son, Ltd., 4, Great Smith Street, Westminster (Teap, 410, pp. 50, with plates and diagrams. 15s. net).

INTERNATIONAL DENTAL FEDERATION.

80 million gallons were pumped daily for purification by reservoir storage, but the cost of coal and its scarcity in the war led to the substitution of chlorination, and that has been so effective as to be still continued. The coal saving last year was £21,000, and this year will be over £16,000. The dose of chlorine is very minute—barely one part in two millions—but in respect of bacteria it improves the water continued, and water long stored in Staines Reservoir is supplied instead. About half the water supply from the Thames is not chlorinated, but purified by storage and slow sand filtration at Southwark, Vauxhall, Chelsea, and Lambeth. Long stored water does not block and involve removal of filter beds, as raw water does. Filtering of water from Walton Reservoir can go on for months instead of for weeks without requiring attention. Storage also slightly softens water, and so would save soap if the fact were domestically recognized.

Sir Alexander Houston concludes his graphic picture of London's water supply by asking his readers to compare a vision of vast underground lakes feeding surface rivers; of deep wells of great purity; of imperfect sources of supply purified either in enormous artificial lakes covering 2,000 acres and holding nearly 13,000 million gallons, or by chlorination; and of water finally delivered to consumers after slow sand and filtration.

The second annual meeting since the war of the International Dental Federation was held at the Sorbonne, Paris, from August 6th to 10th. The meeting was opened by M. Mannoury, Minister of the Interior, in the absence of the Premier, M. Poincaré, who was unable at the last moment to attend.

The Minister of the Interior was supported by Dr. Truman W. Brophy of Chicago, President; Mr. W. B. Patterson of London, Honorary President; Messrs. Blatter, Georges Villain, M. Roy, and Professor Vian, of Paris; Messrs. J. H. Mannoury of London, Walter Harrison of Brighton, and Professor Gilmore of Liverpool, Dr. W. Guy and Mr. J. A. Amoreo (President-elect of the British Dental Association) of Edinburgh, Dr. Florestan Aguilhar of Madrid, the Secretary-General, Dr. Wheeler of New York, Dr. Dubau of Montreal, Dr. Edward C. Kirk of Philadelphia, Dr. Potter of Boston, U.S.A., and many others.

Dr. Aguilhar, the Secretary-General, described to the meeting the terrible state of poverty and starvation in which he had found many of the once leading dentists of Petrograd and Moscow; and as a result of a visit to those cities during the past winter he had, in the name of the Federation, advanced several hundred pounds to be distributed to dentists through the Committee of Dr. Nansen's fund.

The President of the Federation detailed the work of the Federation since its last meeting, and made reference to the possibility of some financial co-operation with the Rockefeller and Carnegie Trusts funds for the purpose of spreading abroad generally the considered opinions of the Federation on dental education and dental hygiene. M. Mannoury eulogized the work of the medical officers of the public health service in France. Their work was conducted with efficiency and economy, and under it he owing to the results of the war, but nevertheless it was included such public dental services as were possible. Moreover, he said, might be expected year by year as the country improved in prosperity, and on behalf of himself and the Minister of Health he promised that the public health should continue to occupy a first place in all Government measures. From professional bodies, like the Federation, ministers and Government departments welcomed on all occasions counsel and advice. At the conclusion of the Minister's remarks, the representatives in the Federation among which was the speech of Dr. W. Guy of Edinburgh, of some fourteen nationalities made short speeches, chief representing Great Britain. Dr. Guy's eloquence and its

must be sufficiently high, and this meant that the condensers must not be too big. He wished also to say that diathermy and intensive high frequency did have a definite effect upon the growth of bacteria. Twenty-five years ago he conducted a series of experiments with a bacteriologist on the growth of the diphtheria bacillus, and by putting the test tube into the solenoid through which the high frequency current was passing it was evident what an influence the current had on the growth of bacteria, and it might help the growth of bacteria in the body in the same way. Next, Dr. Robinson had pointed out that in gonorrhoeal arthritis, say of the elbow-joint, it was better to treat the source of the poison. There were a very large number of distressing cases of chronic blood poisonings, perhaps of the rheumatic type. Many cases of this kind were due to septic infection of the tonsils, which could be dealt with by surgical means, but there were a series of most distressing cases in which blood poisoning was due to haemolytic streptococci entering the tonsils, and the tonsils were very small and could not be removed, at least without a good deal of haemorrhage. There were a certain number of cases in which tonsillectomy could not be practised. Was there any possibility of surgical diathermy being applied to the tonsil in such cases, to get rid of the focus of infection? The question of high blood pressure was a very difficult one; he quite agreed with Dr. Turrell that very often the patient might be made worse by altering the blood pressure. On the other hand, high blood pressure did mean a state of danger, and if people could be kept below that danger limit their lives would be prolonged. To bring the pressure down too much in an artificial way was to do harm, but there was surely some carefully adjusted method which would be useful. In most cases of increased high blood pressure there was interstitial nephritis. Dr. Howard Humphris had said that general diathermic treatment would increase the elimination of waste products. If that was the case it ought to be followed. In conclusion he referred to the treatment of haemorrhoids by intensive high frequency, a method of treatment he had carried out for twenty-five years, and the more he used it the better he liked it. He had had many cases come back after four, five, or six years with a request for another set of treatments, and the patients had told him that the course he had given them previously had ensured their comfort until then. He usually gave twenty minutes' treatment on a condenser couch for two or three times. The same thing applied to simple congested prostates.

Dr. C. B. HEALD (London) said that the headings furnished by Dr. Cumberbatch provided an excellent basis for discussion, and he proposed following these in the remarks he had to make. With regard to what Dr. Cumberbatch had said about machines, he was convinced that this suggestion for removable ends in the spark-gap was both useful and practical, nor should there be any difficulty in manufacture. He would like to ask Dr. Russ whether anything could be done to prevent sooting up of the spark-gaps; his impression was that this sooting took place more rapidly with some samples of gas. Under his heading of "deep heating" Dr. Cumberbatch had described certain paradoxical effects. The speaker's own clinical experience had taught him that in using diathermy, especially for deep-seated organs, it was not a question of how much current could be brought to bear but of the most suitable quantity and technique. Indeed, he now felt certain that if diathermy was used when acute lymphangitis was present it was essential that small currents and long times should be employed. Dr. Cumberbatch had asked for their experiences in certain special diseases, and he would like to deal particularly with three. With regard to gonorrhoea, he had had the pleasure of receiving instruction from Dr. Robinson in his methods, and so impressed was he of the value of these that he had adopted them as a routine practice at his hospital. He would, however, like to ask him whether in his diathermic treatment of the epididymis he had ever produced sterility or prevented this most common sequel of a gonorrhoeal affection of this organ. He also agreed with him as to the necessity of treating the primary focus in all cases of gonorrhoeal arthritis. With regard to

cold limbs and poliomyelitis, he had a paper on this subject in course of preparation, but he could say there without entering into too great detail that he had met with most remarkable and uniform success, and that if the current was employed by a technique he had elaborated improvement took place even in cases of very long standing. One case he had under treatment at the present time was showing rapid and remarkable progress, although there was a previous history of twelve years without improvement. In lung cases some of the remarkable effects he had seen from the use of the diathermic current and its cousin, the vacuum electrode, could not be accounted for entirely by the heating effect and required further research. Passing to one or two points outside Dr. Cumberbatch's paper, he had been particularly struck by a remark by one of the previous speakers that "Other remedies having failed, the case was presented for electrical treatment." This, unfortunately, was often too true, and the great value that electrical treatment could have in the early or acute stages of disease was too little known or realized. This, however, was their fault as electro-therapists, and it was up to them to educate, by convincing scientific proof, their medical colleagues. The first step in this education must be to prove to them that diathermy not only did not irritate or stimulate when properly applied, but was soothing and sedative. When, however, such a great authority as Sir Robert Jones categorically stated that any form of electrical treatment in the early stages of poliomyelitis was actually harmful, it necessarily followed that cases in the early stage of that disease were rarely referred to the electro-therapist. The speaker, however, had no hesitation in saying that not only would these children benefit by the early application of diathermy, but a material lessening of the crippling effects of the infection might be expected. He thought there was need for scientific investigation of the question whether diathermy did not act also in some manner that was not entirely due to the heating effects of the current. He was, therefore, particularly glad to hear Dr. Batten's observations on Professor Phillipson's recent paper. Finally, he wished to agree most strongly with Dr. Turrell's remarks on the necessity for viewing each case from the physiological and pathological standpoint before any course of electrical treatment was embarked upon. It was in these respects that the non-medically qualified people who used electrical currents were liable to bring the science of electro-therapeutics into danger.

Professor SIDNEY RUSS (Middlesex Hospital) said that, knowing Dr. Cumberbatch as an experimentalist, he rather expected to hear him say that he would like a machine which would give him a bigger range not so much of output as of frequency of oscillation. That was where expansion was required, and if that was secured it would help to clear up one or two points touched upon lightly during the discussion. The heating effect of the diathermy current was, of course, the main reason for its use. Had Dr. Cumberbatch in any cases seen favourable results by the use of the diathermy current when he had reason to suppose that the rise of temperature was insignificant? If so, then the question arose, to what were the results due? It was well known that with this frequency of oscillation practically all ionic movement could be cut out. An oscillating magnetic flux was associated with this current. So far as the speaker knew, there were very few instances in which the oscillations of a magnetic field had any physiological response. The only one which had been demonstrated to the physicist's satisfaction was the experiment of Professor Silvanus Thompson in which there was an effect on the sensation of vision. Here a kind of magnetic flicker went on. If physiological effects were to be observed with these currents with an insignificant rise in temperature he would like to know to what cause the electro-therapeutic attributed them. The ordinary laws of resistance all broke down in the case of these oscillations. It would be very difficult to predict the effect even with metals, and in going through the human body where a passage was made not only from one kind of tissue to another but from solids to gases, he did not wonder that irregularities occurred. He imagined it would be very difficult to predict what the

## THE MODERN CONCEPTION OF JAUNDICE.

WITH the passage of time there is often a swing of the pendulum, so that hypotheses that have been abandoned, if not almost forgotten, come again into favour and fashion, though perhaps in a somewhat altered dress on account of fresh data. This has certainly taken place with regard to the classical theories of jaundice. From the time of Virchow's observations on haematoïdin, an isomer of bilirubin (1847), the older writers believed in the existence of a true haematogenous jaundice without any biliary obstruction and quite independent of any participation of the liver cells. After 1886 a reaction succeeded Almkowalski and Naudyn's experimental removal of the liver in guinea-pigs, which showed that the jaundice which in control animals followed the administration of arsenic failed to occur, and thus suggested that the liver was essential for the production of bile pigment. A little later, in 1891, Stadelmann's experiments with haemolytic agents rendering the secretion of bile excessively viscid, and so obstructing the smallest bile ducts and capillaries, led to the view, set out at length by Dr. William Hunter in the first edition of *Allbutt's System of Medicine* (1897), that all jaundice was obstructive, if not in the larger bile ducts then inside the liver.

The notion of haematogenous or haemolytic jaundice was thus discredited until 1911, when it again came to the fore, and since then has inspired a large amount of research work, with a corresponding alteration in our views as to the mechanism of jaundice; much has been done in America, France, Germany, Holland, and in this country. Dr. J. W. MacNee, who began work on these lines in 1912, has now, in a critical review<sup>1</sup> of the recent advances in our knowledge of jaundice, given an admirable summary of the whole subject; and, as haemolysis and the metabolism of haemoglobin are so intimately connected with jaundice, it is fortunate that Dr. Reynon Rous<sup>2</sup> of the Rockefeller Institute has provided a comprehensive review dealing with the destruction of the red blood corpuscles in health and disease. According to the more modern view the ordinary polygonal cells of the liver do not form bile pigment from effete haemoglobin; this is carried out by the reticulo-endothelial system, the constituents of which are exemplified by Kupfer's cells in the liver and the haematophagous cells of the spleen. In birds these cells are mainly in the liver, the spleen being small, whereas in mammals and man this distribution is reversed. In confirming the absence of jaundice in hepatectomized geese poisoned by arsenic Dr. MacNee argued that the jaundice in this result was due to removal of the Kupfer's cells, and that the geese's liver contains two categories of cells distinct in function—the endothelial and the parenchymal. The polygonal liver cells, however, appear to play the part of receiving the bile pigment

formed by the cells of the reticulo-endothelial system and of passing it on to the bile capillaries after modifying its constitution. To these two functions of the liver cells attention may now be briefly directed. The French school, and especially Brule (whose monograph was noticed in our columns),<sup>3</sup> insist that functional disorder of the hepatic cells may result in being shunted into the blood vessels instead of into the bile capillaries; the influence of functional disturbance rather than of mechanical obstruction, for example, in so-called catarrhal jaundice, is emphasized. The conception of dissolved jaundice—namely, when bile pigment without bile salts, or vice versa, is retained in the blood—thus arose, and is regarded as characteristic of hepatic insufficiency. In connexion with the changes effected in the bilirubin by the liver cells the test elaborated by Professor Eliasson van den Bergh, now of Utrecht, for the detection of bilirubin in the blood serum, has most important bearings. It shows that there are two forms of bilirubin. One form gives an immediate reaction with Ehrlich's diazo-reagent, and occurs in obstructive jaundice—that is, when the bilirubin has passed through the polygonal cells of the liver and has then been absorbed on account of obstruction; this prompt (or immediate) direct reaction is given by the bile in the gall bladder. The other form of bilirubin gives no colour reaction, or only after a long delay; this is the delayed direct reaction, and occurs in the serum in non-obstructive jaundice, and in haemorrhagic effusions in the chest and abdomen, when presumably the bilirubin, formed by the cells of the reticulo-endothelial system, has not been modified by passage through the liver cells. In addition there is a biphasic reaction, probably due to the presence of both forms of bilirubin in the blood serum, as in some cases of catarrhal jaundice in which there is a combination of obstructive and toxico-infective factors. It should be added that every icteric serum gives an immediate colour reaction with the diazo-reagent after treatment with alcohol—van den Bergh's indirect reaction. Quantitatively van den Bergh's test shows that bilirubin is normally present in blood serum in the proportion of from 1 in 1,000,000 to 1 in 400,000, and that when it reaches 1 in 50,000 bile appears in the urine; below this figure there may be latent jaundice, either haemolytic, as in pernicious anaemia, icterus neonatorum, and helminthic anaemia, or obstructive, as in cirrhosis. In obstructive jaundice the colour of the skin gives no indication whatever of the bilirubin content of the blood serum; for example, in chronic black jaundice the bilirubin content may be much less than early in the course of the disease when the yellow tinge is just appearing.

Dr. MacNee divides jaundice into three groups: (a) obstructive; (b) toxic and infective, by far the largest, in which the van den Bergh test gives variable results, and in which the biphase reaction was first described; and (c) haemolytic. In the toxic and infective jaundice it is probable that both obstruction in the bile passages from cholangitis and damage to the polygonal liver cells play a part, preponderating in one way or the other at different times. Into this critical review Dr. MacNee has introduced a model of what such an article should be.

of oscillation of the current played an important part in the distribution through the tissues. In the case of tonsil infection, mentioned by Dr. Batten, he would suggest the excision of the tonsils by means of the diathermy knife electrode. He was cordially in agreement with Professor Russ on the point that when cases were described not only the strength of the current but its density should be mentioned. With regard to Dr. Stoney's remarks, chilblains would be removed by applications of diathermy, but if the cause of chilblains still remained they would recur.

## SECTION OF DISEASES OF CHILDREN.

EDMUND CAUTLEY, M.D., F.R.C.P., President.

### DISCUSSION ON ACIDOSIS AND ALKALOSIS IN CHILDREN.

#### OPENING PAPER

BY

P. J. CAMMIDGE, M.D. LOND.

BEFORE we can profitably discuss acidosis and alkalosis it is essential that we should have a clear conception of what we mean by the terms, as they are frequently employed by clinicians and laboratory workers in different senses. The theory of acidosis was introduced into medicine to explain diabetic coma, which it was believed arose from the presence in the blood of abnormal acid products of metabolism, notably beta-hydroxybutyric acid, in an unneutralized condition. Since this substance was found to be excreted in the urine along with acetone and aceto-acetic acid, acetonuria came to be looked upon as an index of acidosis, and the terms are still regarded as synonymous by some clinicians; it will save possible difficulties, however, if we agree to refer to this condition simply as acetonuria, or, better, ketonuria. Subsequently means were sought by which the degree of acidosis could be easily determined, and, as direct measurement of the acid products proved impracticable, reliance was placed upon an increased elimination of ammonia by the kidneys. Such an increase usually takes place when there is an undue formation of acid products in the metabolic cycle, but, as it was found that the acids are not necessarily of the group referred to, acidosis with, and without, ketonuria were eventually recognized. At a later date, when the essential characters of acids and bases had been worked out and new and more delicate methods of blood analysis were developed, the subject was investigated from a fresh point of view. At first it was hoped that determination of the acetone content of the blood would be helpful, but it proved a fallacious guide. The same was found to be the case with the titratable reaction, which, it was shown, undergoes very slight alteration in even the most severe forms of clinical acidosis; in fact, so carefully is the reaction of the blood regulated that it has been suggested by Hawk<sup>1</sup> that a change equivalent to the very slight difference between the reaction of tap water and distilled water might prove fatal. In the light of this discovery the old idea of acidosis, in the sense that the symptoms associated with it are dependent upon the presence of unneutralized acid products of abnormal metabolism in the blood, had to be abandoned and replaced by a new conception.

In order to obtain a clear understanding of the views which now arose it is necessary we should briefly consider the mechanism by which the normal, faintly alkaline reaction of the blood is maintained. It is essentially a physico-chemical process, depending upon the interaction of alkalis with acids, of which carbonic and phosphoric acids are the most important. Weak acids such as these possess the interesting property of maintaining the reaction of the fluid in which they occur at a practically constant value if an excess of their salts is also present; any added acid or alkali is, as it were, soaked up, hence they are known as "buffer substances." Owing to the presence of substances

of this character in the blood considerable quantities of acid or alkali can be dealt with without any alteration taking place in its reaction, and if the mechanism for renewing the supply and removing the products formed is working efficiently, the process can continue indefinitely. In ordinary circumstances the necessary supplies are derived from the food. On a mixed diet there is a tendency towards the constant production of an excess of acid radicals, which are, however, oxidized or neutralized and then eliminated, the organic acids being converted into carbon dioxide, and the mineral acids combined with ammonia, when a sufficiency of bases coming from the food is not available, or with colloids, the amphoteric nature of which enables them to take up a considerable amount of acid or base without altering their reaction. Removal of the end-products produced in this way is effected by the lungs, through which carbon dioxide is eliminated; by the kidneys, which excrete most of the fixed acids; and by way of the intestine, through which some of the phosphoric acid passes out from the body. Very little is known of the part the intestine plays in regulating the reaction of the blood and tissues, although it is probably more important than is generally supposed. The efficient functioning of the kidneys is a cardinal factor, but their influence is exerted comparatively slowly and the amount of acid derivatives they can excrete is not large relatively to the quantity calling for removal in some pathological conditions. The most important regulating mechanism for rapidly controlling temporary variations is the excretion of carbon dioxide by the lungs.

When the entrance of acid products into the circulation disturbs the equilibrium existing there between the carbonic acid and bicarbonates, by decomposing some of the latter and producing a relative excess of carbonic acid, the increased acidity which would result is prevented by the sensitiveness of the respiratory centre to changes of reaction in the blood. It at once speeds up pulmonary ventilation and thus eliminates carbonic acid until its original ratio to the bicarbonates is restored, but, as there is less bicarbonate than before, the proportion of carbonic acid will also be lower and remain so until the destroyed bicarbonate has been replaced from the alkaline reserves of the body. In a healthy individual this is quickly accomplished, and the alkaline reserve is replenished from the bases contained in the food; but when, as may happen under pathological conditions, large amounts of acid are continually entering the circulation, the supply may not be equal to the demand. The alkaline reserve is then gradually depleted, the proportion of bicarbonate in the blood is permanently diminished, and there is a corresponding reduction in its capacity to transport carbon dioxide, which consequently accumulates in the tissues, giving rise to the subjective symptoms of suffocation, with hyperpnoea or air hunger, followed eventually by death when the exhaustion of the alkaline reserve is sufficiently extreme. According to modern views, therefore, the cardinal feature of acidosis is not an excessive production or accumulation of acid in the body, but a diminution of the reserve supply of alkali-yielding substances arising from the attempt to prevent acids appearing in the circulation as such; and since the proportion of bicarbonate in the blood represents the excess of bases left, after all the fixed acid has been neutralized, acidosis has been defined as "a condition in which the concentration of bicarbonate in the blood is reduced below the normal level." It will be noticed that no reference is made to acetone bodies or the excretion of ammonia, although an acidosis associated with ketonuria and an increased ammonia output in the urine is covered by both definitions. Various subdivisions of acidosis, such as compensated and uncompensated, relative and absolute, and alkalipenia or diminution of the alkali reserve, have been introduced to describe particular forms arising in special circumstances. For our present purpose, however, it will be sufficient if we agree on the fundamental feature of acidosis as it is now understood—namely, a diminution of the alkaline reserve of the blood and tissues—and only use the term in that sense, modifying it by the adjective "mild" or "severe" as may be necessary. In order to provide for the rare condition where there is an actual change in the reaction of the blood toward the acid side we may speak of an acidemia. Alkalosis is the antithesis

INSULIN IN AMERICA.

In the *Canadian Medical Association Journal* for July, 1923, the Insulin Committee of the University of Toronto reviews the therapeutic value of insulin in diabetes, its action, and its manufacture. The now familiar history of the discovery of insulin is summarized, beginning with the experiments of von Mering and Minowski, who first established the important relationship between the pancreas and diabetes. Attention is drawn to the excellence of the team work, which in the later stages of the investigation in Canada showed such good results in a comparatively short space of time. It is again emphasized that medical practitioners must not conclude that insulin can replace the dietetic treatment of diabetes mellitus, and that the indiscriminate use of insulin in cases of diabetes is a real source of danger. Hitherto the most brilliant results obtained with insulin have been in the treatment of diabetic acidosis and coma; in such cases it must be given immediately. The article in our contemporary describes the care that was taken by the University of Toronto to ensure the proper manufacture of insulin, and to provide for the control of its distribution among the medical profession. In order to obtain insulin on a large scale in America an arrangement for its manufacture was made first of all with the firm of Eli Lilly of Indianapolis, who also distributed the drug to a large number of physicians for clinical trial. When, however, a satisfactory process had been worked out for the preparation of insulin on a large scale it was decided to grant licenses to manufacture the drug to other firms who were able and willing to comply with certain conditions imposed by the Insulin Committee. That the policy of the Committee was justified is shown by the statement that several firms in America have exploited for the treatment of diabetes entirely worthless preparations, to which the impression that these contained the antidiabetic hormone. But for the conditions imposed the market would probably by now have been flooded with preparations of unknown potency and durability, and serious accidents would certainly have resulted. At the end of the article a full bibliography is given of the literature dealing with insulin published up to the present time.

INTERNATIONAL CONFERENCE OF RED CROSS SOCIETIES.

The eleventh International Conference of Red Cross Societies, organized by the International Red Cross Committee, was held at Geneva on August 28th and following days. The first of these conferences took place in 1863 as the outcome of Henri Dunant's *Souvenir de Solferino*, and led to the diplomatic conference which framed the Geneva Convention of 1864 to ameliorate the sufferings of sick and wounded in war. Periodical conferences subsequently fell into abeyance for fifteen years during and after the Franco-German war of 1870-71; they were revived in 1884 and were held every five years in the capitals of European countries until 1912, when the ninth conference was held in Washington. The great war then intervened and the next conference was not held until April, 1921. By that time the League of Nations and the treaty of Versailles, had established itself in Geneva and seemed to overshadow the old International Committee. But the spheres of work of the two organizations were adjusted by mutual agreement during the conference of 1921: the League confining its activities to international health propaganda, child welfare, and disease prevention in time of peace, and the International Committee to maintaining solidarity amongst the National Red Cross Societies, as an offshoot of the League of Nations.

"BROWN HEART."

We understand that the National Council for Combating Venereal Disease, and the Society for the Prevention of Venereal Disease, each of which has considered and unanimously accepted the Trevethin Report, have decided to confer together in order to determine what joint action can be taken for giving effect to the recommendations contained in the report. This conference will probably be held after the summer vacation. A full account of the findings of Lord Trevethin's Committee and its recommendations was published in the *British Medical Journal* of June 6th, 1923 (p. 976). In discussing the report on June 16th we expressed the view that it provided a starting point for work towards the common goal of reducing the incidence of venereal disease to negligible proportions, and that it ought to be the means of ending unfortunately, controversies which have so prejudicially affected the campaign against this disease in the near past. The two societies working together. The public has a right to expect guidance and assistance from a united profession; we hope, therefore, that the forthcoming conference will be the prelude to active co-operation.

CONTROL OF VENEREAL DISEASE.

latter aspect of Red Cross activity with which the International Conference of Red Cross Societies, which now meets every two years, is chiefly concerned. One of the principal matters before the eleventh conference is the history of efforts which have been continued during the present year to bring about a fusion of the League of Red Cross Societies and the General International Committee. These efforts have—according to a statement published in the *New York Herald*—so far failed. In this connection it may be recalled that the voluntary aid organizations of Great Britain took no part in the International Conference of Red Cross Societies until 1907, although a War Office or Government delegate was appointed to attend each. When, after the South African war, the National Society for Aid to Sick and Wounded in War was reconstituted as the British Red Cross Society, it began to take an active part in the conferences. We understand that the British Red Cross Society will be represented next week by Sir Edward Stewart, and the War Office by Sir W. G. Macpherson; each attended the last conference in a similar capacity. It is expected that the Red Cross Societies of the Dominions also will be represented again.

"Brown heart" is not another calamity that has to be added to the list of the many ills that afflict humanity. It is the name given to a functional disease of apples and pears, as the result of researches carried out during the past four or five years by Drs. Franklin Kidd and Cyril West on behalf of the Department of Scientific and Industrial Research of the Food Investigation Board. An account of their work has just been published, and is of great interest from the physiological, pathological, and economic standpoints. The condition was first observed in 1918 in the course of experiments conducted with the object of investigating the retarding effect of carbon monoxide and subnormal oxygen upon the ripening of apples as a cheap method for preserving the home-grown apple crop in storage. It was then observed and since confirmed that "brown heart" appeared in apples stored in the presence of carbon monoxide above a certain concentration, combined with a subnormal oxygen concentra-

Special Report No. 12. Obtainable from H.M. Stationery Office Publishing Department, Imperial House, Kingsway, and from the chief publishers in New Zealand, Johannesburg, Calcutta, Bombay, and Madras, at 7s. 7½d.

I do not propose to discuss the large variety of diseases in which acidosis may arise in children and materially add to the gravity of the condition individually, as they will no doubt be much better dealt with by those who have had greater experience of children's diseases. I shall confine my remaining remarks to two groups of cases, which have particularly come under my notice—namely:

(1) Those in which there is definite evidence of defects of carbohydrate metabolism—in other words, frank diabetics.

(2) Children suffering from recurrent "bilious attacks," with vomiting and transient ketonuria.

It is important that it should be generally realized that diabetes, or glycosuria, in children as in adults, is not a disease in the sense that it is always dependent upon the same cause. The investigations upon which I have been engaged for over twenty years have definitely proved that it is a condition which may arise in a variety of ways, and twelve types can now be differentiated. In some of these ketonuria and acidosis develop at an early stage, in others they are only met with as a terminal complication, the chief determining factor being apparently the functional efficiency of the liver. As long as the liver is able to perform its part in metabolism satisfactorily there is no fear of acidosis, even though there is pronounced hyperglycaemia and glycosuria; but when, owing to congenital defects, acquired deficiencies, or secondary disturbances in its functions, the liver is unable to carry out completely the chemical changes it normally performs, so that unusual acid products enter the circulation, the alkaline reserve of the body soon suffers and acidosis develops. These points were well illustrated by a partially depancreatized dog I had the opportunity of observing. In spite of a fairly high blood sugar and the constant presence of sugar in his urine, he appeared in good health and showed no evidence of acidosis until he was given a series of injections of hydrazine phosphate, a drug which is known to have a specific toxic effect upon the liver; he then rapidly developed the signs of acidosis and ultimately died of diabetic coma, the carbon dioxide of his blood falling from 81.5 to 45 per cent. and finally to below 30 per cent.

It is generally assumed that the depletion of the alkaline reserve which occurs in diabetic acidosis is entirely dependent upon the formation of acid products of imperfect fat metabolism, but the whole-blood analyses I have made in a large number of cases suggest that this is not the only explanation and that incompletely utilized protein derivatives are a contributory factor; also that in some instances defects in the excretory functions of the kidneys, similar to those met with in interstitial nephritis, accentuate the acidosis. In many cases, too, analysis of the faeces reveals an inorganic ash content considerably in excess of the normal, pointing to there being an abnormal excretion of bases through the bowel wall, a condition which would serve to diminish the alkaline reserve still further. It is not surprising, therefore, that acidosis of an advanced type, in which several of these factors are probably at work, is difficult to control, and especially in children, whose metabolism is less stable than in adults, as is shown by the fact that comparatively small changes in the diet of a diabetic child will often produce very striking results. Thus I have seen the addition of a single egg, or a dose of cod-liver oil, induce a ketonuria, which rapidly disappeared when the addition was discontinued. But such a result is not inevitable; it depends entirely on the type of case and the stage of the disease.

In the earlier stages of diabetic acidosis suitable regulation of the diet brings about a rapid improvement, and even in the more severe types the alkaline reserve can usually be brought back to the normal by appropriate treatment, if serious organic changes have not taken place in the liver and sufficient glycogen can be laid down. It has frequently been stated that diabetes in children is a hopeless condition, especially when there is acidosis and ketonuria, but, although this might have been true at one time, it is not the case now. I have records of over a dozen children under the age of 12 who are alive and well at least three years—in one instance ten years and in another twelve years

—after I first saw them, in spite of the fact that they exhibited evidence of acidosis and were suffering from pronounced glycosuria. In all of the more recent cases, where it has been possible to employ modern methods of investigation, the metabolic changes have proved, however, to be largely the result of functional disturbances, and there has been no evidence of serious organic mischief in the liver or pancreas. When there are permanent defects in these organs the problem is more difficult, and only temporary improvement can be effected, even with the most recent methods of treatment. The introduction of insulin has placed at our disposal a powerful weapon for dealing with acidosis dependent upon defective glycogen storage, but unfortunately, its effects are only temporary in the majority of cases.

Take, for example, the case of a boy, 11 years of age, who was brought to me in January with a history of diabetes of two years' duration. His blood was then found to contain 0.36 per cent. of sugar, while the carbon dioxide tension of his alveolar air stood at the very low figure of 16 mm. After the injection of 25 units (old style) of insulin the carbon dioxide tension rose to 25 mm. and the blood sugar dropped to 0.30 per cent. in three hours. As the result of continued treatment with insulin, combined with dieting, during the following three weeks his blood sugar fell to 0.11 per cent., and the carbon dioxide tension of the alveolar air increased to 34 mm. Yet within a month of the injections of insulin being discontinued the blood sugar had returned to almost its original level, the carbon dioxide tension had diminished to 25 mm., and examination of a twenty-four hours' collection of the urine showed 1.96 grams of ammonia nitrogen and 2.3 grams of oxybutyric acid, in spite of every care being taken with the diet. A fortnight later the ammonia excretion in the urine had increased to 2.3 grams and 22 grams of oxybutyric acid were being passed.

The second group never exhibit the pronounced acidosis met with in some diabetics, but there is always evidence of a reduction of the alkaline reserve, particularly during an attack. The patients coming under my observation have varied in age from 2 to 12 years. As a rule they would seem to have been healthy infants; then, for no apparent reason, they commenced with febrile attacks, associated with loss of appetite, general malaise, sickness, and headache, which persisted for several days and recurred at intervals, generally of progressively shorter duration. During an attack examination of the urine shows the presence of acetone bodies, and, although Fehling's test is usually negative, or gives a doubtful reaction, Benedict's test often reveals traces of a reducing substance. It is a type of case with which everyone is no doubt familiar, and my only reason for referring to it is that I have been able to carry out more elaborate analyses than are usually performed. Let us consider an illustrative example.

In March, 1922, I was asked to advise regarding a boy, aged 11, who had been treated by several physicians for attacks of the type to which I have referred, which had commenced about three years previously and had recently become more frequent and severe. A twenty-four hours' collection of his urine, made towards the end of the attack from which he was then recovering, showed 0.8 gram of acetone, a total acidity of 600, an ammonia nitrogen of 0.79 gram, 0.35 gram of amino-acid nitrogen, 2.1 grams of sugar, a considerable excess of urobilin, and gave a pronounced reaction for indican. Two days later another collection of the urine, made on a test diet containing 70 grams of carbohydrate, 45 grams of protein, and 35 grams of fat, was found to be free from acetone and to show a lower total acidity (400) and ammonia nitrogen (0.59 gram), but still to contain a trace of sugar (1.9 gram). Examination of the faeces revealed no striking abnormality macroscopically or microscopically, although chemical analysis showed that there was 22 per cent. of inorganic ash, an excess of combined fatty acids relative to unsaponified fat, and a marked reaction for biliverdin. From these results it seemed probable we had to deal with a case in which there was a chronic catarrh of the small and large intestines, with abnormal decomposition in the contents of the upper bowel and interference with the functions of the liver, giving rise to ketonuria and slight alimentary glycosuria. A full analysis of a sample of blood taken from a vein before breakfast tended to confirm these conclusions, for it showed an excess of uric acid (4.5 mg. per cent.), amino-acid nitrogen (9 mg. per cent.), ammonia (0.9 mg. per cent.), and phenols (14 mg. per cent.), while a low calcium content (2.5 mg. per cent.) suggested a possible explanation of the bleeding from the nose to which the patient was liable, and the presence of only 48 volumes per cent. of carbon dioxide showed that there was mild acidosis.

*Guy's Hospital Reports* and elsewhere. In a recent paper with the rather formidable title "Heteromorphosis (metaplasia) of the alimentary tract," he contends that the only way to understand gross malformations, such as monsters, originating during embryonic life is the investigation of the very simplest anomalies due to pathological states, or the heteromorphoses. The distinction generally drawn between congenital anomalies and those acquired later is to his mind purely artificial, since every malformation must originally have been acquired. Underlying the article is distrust of Colubich's theory of tumours as due to focal displacement of cells, as is shown by the dictum that "displaced and undifferentiated cells, if ever, exist except in the imagination." Special means of villous duct, Meckel's diverticulum, pancreatic cyst, inflamed gall bladder, and tuberculous ulcer of the colon, all showing gastric mucous membrane, are described to support the argument that inflammation produces the changes in the epithelium and that there has not been a displacement of gastric "rests" into these various situations. Chronic inflammation first causes active proliferation of the epithelial cells and de-differentiation or a regressive change, but this may in abnormal circumstances be succeeded by differentiation, or more correctly a re-differentiation, since there was a preceding de-differentiation of the epithelium, which has retained its prospective potency to undergo differentiation into gastric mucous membrane. The changes described in cholecystitis are specially interesting; out of 35 inflamed gall bladders 24 contained mucous glands, which are normally present only in its neck, and 17 of these showed gastric glands as well; it is argued that the gall bladder has throughout life the potentiality of forming gastric glands; normally this capacity remains latent, but it is readily roused to activity as a result of the proliferation involved in cholecystitis. The study of de-differentiation and re-differentiation as the result of inflammation has a most important bearing on tumour formation, and it is to be hoped that Dr. Nicholson will continue his efforts to throw light on this difficult problem.

#### THE EDUCATIONAL NUMBER, 1923.

Our next issue, dated September 1st, will be the annual Educational Number of the British Medical Journal. The usual features will be supplemented by two introductory articles on certain aspects of the training of the medical student, contributed at our request by Sir George Newman and Dr. J. S. Fairbairn. The former writes on the permeation of the medical curriculum by preventive gynaecology, in their insistence on the need for preventive teaching, these articles are complementary to each other. The concise information annually provided for intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the various medical schools and kindred institutions. A full account is given of the important changes that have been introduced this year into the scheme of study and examination in accordance with the resolutions and recommendations of the General Medical Council. Among the sections which have been rewritten or largely recast may be mentioned those on post-graduate study in London, and on the present and future of psychological medicine; also the introductory note on professional study and practice, addressed mainly to prospective students and their parents. The Educational Number for 1923 will include also articles on the various public services, on the medical education of women, on tropical medicine, on dental study and practice, and on

G. W. Nicholson, *Journal of Path. and Bacteriol.*, Edinburgh, 1923, xxvii, 359-417.

The Museum of the Royal College of Surgeons of England, in Lincoln's Inn Fields, has recently been enriched by the addition of a series of very primitive surgical instruments used at the present day by the Shawiya, a Berber tribe living in a remote part of Algeria. The donor is Captain M. W. Hilton-Simpson, B.Sc., author of *Liby Medicine and Surgery*, a work which describes these uncouth contrivances, with illustrations; it was reviewed in our issue of February 17th, 1923 (p. 291). Though very roughly fashioned, the instruments appear to be strong and serviceable, and include the primitive bone-saw known to Ambrose Pare and modified by Hey as the saw which bears his name. This collection forms an instructive contrast to a set of ophthalmic instruments used in the island of Cele, probably during the Venetian occupation, and remarkable for their artistic finish. They were collected in Cele, seventy years ago, by Admiral Spratt, C.B., F.R.S., and recently presented by Colonel Spratt-Bowring, C.B.

#### PRIMITIVE SURGICAL INSTRUMENTS.

The numbers of the medical profession. The requirements of the universities and other licensing bodies, and the opportunities offered by the medical schools and teaching institutions of the British Isles, are summarized upon the plan followed in recent years. The "preventive idea," dwelt on by Sir George Newman in his opening address, will be found reflected in various parts of the issue, more particularly in the articles on the revised curriculum and on the public health service.

**VOLUNTARY BOARDERS IN MENTAL HOSPITALS.** In his report for 1922 Dr. A. D. Townsend, medical superintendent of the Barnwood House Hospital for the voluntary boarders. As many as nine patients, after de-certification upon recovery, elected to remain as voluntary patients for the whole or some part of the year, preferring a further residence in the hospital before returning to home life. In regard to the position of voluntary boarders generally, Dr. Townsend expresses the hope that greater latitude will be granted to medical officers. Existing regulations should, he suggests, be so modified that certification of a boarder only becomes necessary in very exceptional circumstances. In support of this view he quotes the case of a voluntary patient suffering from depression and apprehensions, whose mental symptoms suddenly became so acute that, as the law now stands, certification or discharge was necessary. Being unfit for discharge she was thereupon certified, much to the distress of her husband and relations. Within a fortnight of certification she had completely recovered. Experience of other cases persuades Dr. Townsend that some change in the regulations regarding voluntary patients is called for. In this connection we recall that the Board of Control in its last annual report recommended that a voluntary boarder in a registered mental hospital or licensed house should never be placed under certification while in residence unless such a course is absolutely necessary for the safety of the patient or the protection of the public.

#### LONDON POST-GRADUATE COURSES.

Special courses in general medicine and surgery, cardiology, dermatology, diseases of children, ophthalmology, pathology, and other subjects have been arranged up to June, 1924, by the Fellowship of Medicine and Post-Graduate Medical Association. The programme for next month will include a two weeks' course in general medicine and surgery, from September 10th to 22nd, at the Hampstead General Hospital in conjunction with the Hospital for Epilepsy and Paralysis, Midway Vale, the North-Western Fever Hospital, and Paddington Hospital, and on

them calcium, that might be the real cause of this type of tetany. He mentioned a case of tetany under his care which had a gastro-colic fistula, through which the patient lost valuable HCl in the stools. MacAdam and Gordon's case of periodic vomiting, in which there was fairly good evidence of alkalaemia, was of interest in view of Haldane's experiments with ammonium chloride and calcium carbonate. Ammonium chloride was commonly given in these conditions, and Haldane found an increase of fixed acid in the blood when this substance was taken by the mouth. With ammonium chloride the ammonia was converted into urea, so that the HCl was free in the blood. Similarly with calcium chloride the blood was flooded with HCl, calcium being excreted by the bowel as calcium carbonate. In two cases of acute rickets Mr. Osman, working with Mr. Burgess at Guy's Hospital, had found a marked fall in plasma bicarbonate, which could not be accounted for by the slight ketosis present in one of them. He doubted whether this diminished plasma bicarbonate was really the cause of the disease; it was more likely a collateral phenomenon due to alteration in the proportion of the mineral constituents of the blood. Finally, Dr. Poulton doubted whether either acidaemia or alkalaemia by itself was of so much significance in disease as had often been considered. Alkalaemia of measurable degree could be readily produced by taking large doses of sodium bicarbonate. With Campbell Hunt he had found roughly the same degree of acidaemia in bronchitis and emphysema, in diabetics recovering from coma, and in uraemic coma, though the symptoms were very different in these cases; but a warning should be given that there were great difficulties in determining accurately the reaction of the arterial blood at the present time.

Dr. ERIC PRITCHARD (London) asked what practical value could be got out of this academic discussion. He agreed that the commonly held view that acidosis and ketosis were the same obscured the real significance of acidosis. Health in children depended almost more on the extent of the alkaline reserve than on any other factor. It was important to find out under what conditions this reserve was reduced. If acids were produced during metabolism they must be neutralized. Unless they were excreted the result would be an increase of fixed acids in the blood. The kidneys were not the only means of getting rid of metabolic products; surely more importance should be attached to the faeces. In rickets, for instance, a striking feature was the fatty stool. Bases were excreted in combination with the fatty acids in the faeces, and the alkaline reserve was thus rapidly depleted. The presence of fatty acids in the faeces might be due to unabsorbed fat; or fatty acids might be produced by internal metabolic processes, neutralized, and then excreted by the intestine. That the latter was possible was shown by Heidenhain, who isolated a loop of intestine and found after seven or eight days that it contained faecal matter similar to that in the rest of the gut. Non-volatile acids appeared to be present when there was incomplete combustion of food. If a child was allowed out of doors after being kept in a warm room its metabolism was doubled. Substances which were not metabolized appeared in the faeces. Reduction in the alkaline reserve was the result of defective oxidation and excretion of fats by the intestine. Defective oxidation followed overfeeding and absence of fresh air and sunlight. Dr. Pritchard then discussed calcium metabolism. The amount of calcium required in the general metabolism in infants was 0.2 gram in twenty-four hours. If the blood was not able to supply this it was taken from the tissues, especially from the bones. Infants were born with a calcium reserve in the bones, but in premature infants there was no such reserve. In them there was danger of calcium starvation.

Dr. CATHERINE CHISHOLM (Manchester) said that the readers of the papers threw light on various phenomena observed by clinicians. Tetany in marasmic infants she had been accustomed to regard as a result of parathyroid defect. Now it appeared also to be due to alkalosis. Was the parathyroid action that of producing an alkalosis? Would, therefore, this condition be relieved by adminis-

tering acids? The relief produced in some forms of pneumonia, particularly after infections such as measles, was, in her experience, often relieved by large doses of sodium bicarbonate. Presumably this was because it relieved the acidosis.

Dr. CAMBRIDGE, in reply, said that to do justice to a subject of this description it would be necessary to use terms which it would be very difficult for anyone not trained in the latest developments of chemistry to understand. He had therefore tried to simplify the subject and had excluded any unfamiliar expression. For this reason he adopted a classification obvious to everyone. He had been obliged to use the words "acidosis" and "alkalosis." They occurred, in fact, in the title of the discussion. Inorganic salts in the body bore a fixed relation to each other. If this were altered the tissues did not function normally. He had proved this experimentally by perfusing livers with solutions containing various proportions of salts. He could alter the rate of glycogen metabolism according to the solution used. With regard to calcium, it was normally contained in the blood in saturated solution. It was excreted by the intestine. In chronic colitis, as also in some other conditions, and often in diabetes, the faeces contained a high proportion of inorganic ash. This was excreted chiefly in combination with fatty acids. Calcium in the blood was diminished after removal of parathyroids and increased by subsequent parathyroid feeding. The magnesium in the blood was also affected. Injection of magnesium salts produced anaesthesia. Tetany could also be stopped in that way.

#### COW'S MILK IN INFANT FEEDING.

BY

COLONEL R. J. BLACKHAM, C.B., C.M.G., C.I.E.,  
D.S.O., M.D., M.R.C.P.E., F.R.F.P.S., D.P.H.

CONSIDERABLE publicity has been given in the lay press to the statement of Dr. Eric Pritchard at the National Conference on Child Welfare, held in London at the beginning of July, to the effect that the giving of cow's milk to infants was equivalent to infanticide, as the infant could no more digest cow's milk than it could digest lobster. Such a statement, taken apart from the rest of the distinguished pediatrician's address, naturally appealed strongly to the lay reporter, but conveys an impression to the public mind which was quite different from that actually conveyed to Dr. Pritchard's audience, of which I happened to be one. The general impression conveyed to my mind by the first day of the conference was the need for emphasizing the value and necessity for breast-feeding.

The feeling of that conference was that not only mothers, but nurses—and even doctors—required education on this important point, and if this be the case I think no apology is needed for introducing at this meeting a short paper on the subject of cow's milk.

Professor Richet of Paris has put the view I should like you to endorse in words which may be freely translated as follows:

"For the newborn infant any method of bringing up except the natural one is detestable. The cleverest chemist will not succeed in inventing for the newborn infant a food superior to woman's milk. To replace the mother's breast, when well supplied with milk, by a feeding bottle or a spoon is a crime. I am so thoroughly convinced of this," he continues, "that I should think a doctor dishonoured if he were to say to a mother: 'What is the use of suckling your child? It is undergoing an unnecessary fatigue. Make haste and dry up your milk and give your child cow's milk, sterilized, condensed, or in powder, and you will see the little one thriving quite as well.'"

Apparently such practitioners do exist, and to those I would say that physiology and medical practice, supported by statistics from practitioners of preventive medicine and fortified by common sense, demonstrate that in order to keep down infantile mortality maternal milk is the first essential, and to give the miniature man or woman the best possible start in life whenever breast-feeding is possible it should be enjoined rigorously, and, if the infant is thriving, exclusively. Nevertheless there are cases, unfortunately only too numerous, in which breast-feeding is impossible. Many modern women are bad nurses: they have some milk,

Metropolitan Asylums Board.

Report for 1922-23.

made for continuing his work were reviewed in consultation with the Ministry of Health and the Medical Research Council. As a result of this it was decided to put the necessary scientific advisory work into commission by inviting the help of several scientists, each expert in his own way, working together as an advisory committee. The committee has now been constituted. Its Chairman is Dr. Foord Cairns, chief medical officer in the Board's infectious hospitals service. The other members are Sir G. S. Buchanan, representative of the Ministry of Health, Professor H. R. Dean (bacteriology), Dr. C. M. Wenyon (protozoology), Professor J. G. G. Ledingham (immunology), Professor Hugh MacLean (biochemistry), and Dr. Major Greenwood (statistics).

the mortality from epidemics of scarlet fever and diphtheria in the London area fell with great rapidity during the early months of 1923. A remarkable feature of the recent group of epidemic years was the large proportion of diphtheria cases. The number of doses of diphtheria antitoxin supplied to the Board's institutions was nearly 120,000 last year; each dose contained 3,000 units. Reference is made to the difficult problem of dealing with cases of cross-infections, of high infectivity, of doubtful diagnosis, and of exposure to infection. Recent experience during the time when scarlet fever, diphtheria, and measles were all prevalent together in London, has shown that in the acute hospitals about 25 per cent. of the total accommodation should be available for isolation purposes. To meet this need the Board has taken steps to provide additional space.

Some idea of the magnitude of the Board's operations and its sphere of responsibility may be gained from the following figures. The district it serves covers 121 square miles, and the population numbers 47 millions. The Board maintains fourteen infectious diseases hospitals, two institutions for venereal diseases and nine for tuberculosis, five mental hospitals, a training colony for improvable imbeciles, and another for same epileptics, five children's institutions, and a training ship. It maintains also a series of dispensaries, and

Metropolitan Asylums Board: Annual Report for the year 1922-23.  
(Published from the office of the Beard, Victoria Embankment, E.C.4.  
(Pp. 251. Price 5s.)

NEWCASTLE ROYAL VICTORIA INFIRMARY.

During the year 11,876 in-patients were treated, and 93,406 new cases were treated in the out-patients' department during the year, the total number of out-patient attendances amounting to 276,079. As compared with three years ago the number of in-patients rose 10 per cent, the out-patients and casualty cases 11 per cent, and operations 19 per cent. As many as 15,669 accident cases were treated, and of this number 1,355 were detained for admission to the wards. The total number of surgical operations performed during the year was 7,631 upon in-patients, and 3,874 upon out-patients. The financial result of the year's working was satisfactory: during 1922, £585,606 was expended for the year amounting to £1,079,057, so that there was a balance of £1,945 on the right side. The cost per occupied bed on non-private expenditure was £12.13, as compared with £12.50 on the right side. The cost

In the medical report of the Infirmary it is noted that diseases of the digestive system were rare and that the most common diseases resulting in the greatest number of deaths were pneumonia and organic heart disease. In the surgical report it is stated that the operations for peritonitis were of minor importance and that the mortality was reduced from 35 to 22.3 per cent. The number of open operations for tuberculous disease of joints was decreased to a minimum; 24 operations were performed for this condition, which contrasts with 61 in 1892. The skin operations were of minor importance and the mortality in this condition, which contrasts with 61 in 1892. The skin

than ever before, and the space at its disposal was often uncomfortably crowded. The pathological report indicates a considerable increase in every part of the work undertaken by the department; the number of necropsies was 465, and the number of clinical reports from the wards, etc., was 1,183. In the bacteriological department 3,371 specimens were received and reported upon during the year.

extensions contemplated include new wards and new departments for out-patients, x rays, pathology, and bacteriology. The Prince of Wales was received at the main entrance

has been written about this product, and one of the most striking things at the National Milk Conference held at the Guildhall last October was the remarkable unanimity of the medical speakers with regard to its usefulness; but I do not think it is sufficiently realized that the product varies considerably in characteristics according to the method by which it is prepared. Two processes of manufacture are now in use. The first of these consists in the rapid drying of fresh milk on rollers heated by water or steam, and the subsequent powdering of the solids thus obtained with or without admixture of lactose; the second in the projection of milk in the form of a fine spray into a chamber with a current of hot dry air, so that the milk solids fall on the floor in the form of fine powder.

The powders produced by these two processes differ not only in physical characters but also in their reaction to rennet. Roller process powders, for instance, are not soluble in cold water, whereas spray powders are soluble; but the most important difference is the fact that whereas the addition of rennet to reconstituted milk prepared from the former variety produces a fine flocculent curd, its addition to a solution of spray process milk powder forms a dense mass identical with that formed in raw milk. This difference is important, for it was the character of the curd described by French writers as "just like human milk" which first led most of us to advocate the use of milk in this form for infant feeding. Another characteristic of dried milk which has always appealed strongly to me is the constancy of its composition. Nothing is more notorious than the variation in the composition of the milk of one cow, but Dr. James Crowther has drawn attention to the remarkable variation in the milk of small herds as well. In a paper read at the National Milk Conference he pointed out that the variation of fat from day to day is not great in either morning or evening milk when considered separately, but as between morning and evening milk the range of variation is relatively enormous.

In regard to vitamins, I might mention that Professor Dreyer of Oxford University has pointed out that it is only the "C" vitamin which is reduced in quantity by heat. It is destroyed altogether by double heating, reduced considerably by the longer periods of heating at low temperature commonly practised, but only slightly affected by rapid boiling or short heating at temperatures near the boiling point. It may be asserted, therefore, that milk loses little of its vitamin content by the process of drying, whereas with commercial pasteurization there is a tendency to reheat the milk in the home and thus destroy all the "C" vitamin. It is suggested that it is twice-heated milk which causes infantile scurvy.

I consider that milk in this form is especially adapted for mixed feeding, in which, perhaps, the best practice consists not in giving breast feeds and bottle feeds alternatively, but at each feed giving first the breasts and then a bottle in which the amount of milk corresponds as nearly as possible to that in which the former was deficient. Frequently the complementary feed, especially in young infants, is very small, and if ordinary milk be used we are faced with considerable difficulties in regard to obtaining it absolutely fresh, while if condensed milk is used wastage is almost unavoidable. Milk powder can be kept in a tin for weeks, and the French authorities strongly recommend it and largely employ it when a complementary ration is required to supplement the mother's milk.

It is obvious from the foregoing remarks that the subject I have ventured to bring before you is one on which strongly divergent views are held by various authorities on both sides of the Atlantic. We have what might be called three distinct schools of thought—namely, the fresh milk school, the condensed milk school, and the dried milk school. Famous names can be found in the members of each school, and it might not be unprofitable in this discussion to bring out the special qualities claimed for each variety, as the best practice may be found in a knowledge of and judicious employment of all three varieties.

Personally, my experience has been chiefly in hot countries, where milk is more putrescible, more sophisticated, and even more liable to contamination than in temperate climates. Under such conditions for infant feeding

one has turned gratefully from the "white sewage" of the bazaars to the comparatively sterile milk powders.

#### DISCUSSION.

Dr. ERIC PRITCHARD (London) said that the statement made by him regarding cow's milk referred only to infants in the first few days of life and to undiluted milk. It came as rather a shock to him that milk had toxic properties. Normally he thought that such substances were broken up and detoxicated in the process of digestion. With regard to the use of condensed milk, when one had pathological cases they had to be fed pathologically. All kinds of milk were useful if properly used.

Dr. CATHERINE CHISHOLM (Manchester) felt it advisable to stress the necessity of teaching medical practitioners and students the principles underlying the maintenance of a good breast secretion. They taught the necessity of breast-feeding, but they were too ready to accept the statement that the milk was insufficient and poor. She felt that all forms of milk could be used by some healthy children, and agreed that all types of preparation had their uses if given according to indication. The difficulty of using dried milk for children with dyspeptic difficulty was that it was not so easy to vary the constituents of fat, protein, and sugar according to the varying necessity of the case.

#### PROGNOSIS AFTER REMOVAL OF SEMILUNAR CARTILAGES.

BY

R. J. McNEILL LOVE, M.B., M.S.LOND.,

F.R.C.S.ENG.,

SURGICAL REGISTRAR, LONDON HOSPITAL.

THE object of this paper is to review the results of a series of cases of meniscotomy and to endeavour to investigate any factors which influence the prognosis after operation. This paper is based upon a series of 50 cases, the majority of which were treated in the army, and owing to favourable local conditions one was enabled to keep the patients under observation for a sufficiently prolonged period while they performed ordinary duties and partook of vigorous exercises—for example, football, swimming, etc.

It was a curious fact that during the Mesopotamian campaign internal derangement of the knee was an epidemic condition, especially prevalent in the autumn. The probable explanation of this was that during the summer months all hostilities automatically ceased and strenuous exercises and games were in abeyance. The result of this inactivity combined with excessive heat was that muscles, ligaments, and other periarticular structures rapidly lost their tone. With the onset of the autumn an active life was abruptly resumed, and as a consequence internal derangement occurred before the structures supporting the joint regained their tone.

That loss of tone is a predisposing cause of internal derangement of the knee is also suggested by the fact that derangement sometimes follows a simple effusion when a sudden strain is thrown on the knee before the effusion has completely subsided. This occurred in one case of this series when internal derangement followed simple traumatic synovitis; the patient slipped into a river and displaced his internal cartilage while struggling out again.

The war in Mesopotamia virtually ended in the spring of 1917, after which the Expeditionary Force became an army of occupation. This obviated the need of continual movement of men, hence after operation men could be posted for duty at base units, and so "followed through" as long as necessary.

Treatment was carried out on the lines now almost universally adopted. After the first attack the limb was splinted, in the hope that adhesions might form and re-fix a separated cartilage to the capsule. It is imperative that reduction of the cartilage is first obtained, and if the cartilage is merely displaced or torn without separation of fragments fixation may then occur.<sup>1</sup> Patients who had suffered more than one attack were strongly advised to submit to operation.

had been made in certain towns by prepaid stamped envelopes addressed to non-subscribers through the local secretaries; but I did not know that by this and the special general meeting at the College of Physicians only £2400 raised—a splendid result; yet when I put forward that we should have an annual dinner, I received little support and none from the officials.

The conference called by the British Medical Association failed because both the present committees of the two medical charities wished to continue their own independent action and many members were afraid of any close connexion with the Association. I believe there is a strong feeling in the profession that there should be only one charitable institution. We are anxious to take away definitely from Epson College that charitable aspect which we are told has been proved to be harmful to the college; and we maintain that while Epson College grants annuities this stigma of charity will remain.

I said at Portsmouth that the administration of the Royal Medical Benevolent Fund is of the same character as it was twenty years ago. This is a fact, and the committee have always been proud of their small working expenses. We must, however, adapt ourselves to new circumstances. Now, if money is required, whether for charity or any other object, money must be expended—as our hospitals are expending in collecting their subscriptions. Further, to make our fund correspond to the needs of the profession, we cannot trespass upon the necessary time required from any honorary secretary, except in an advisory capacity, and the ordinary routine duties of the secretaryship should be undertaken by a permanent responsible official.

I take the liberty to suggest the following four points which should be discussed with regard to the future reorganization of the Royal Medical Benevolent Fund:

- (1) A permanent office is needed for the fund. It is not enough to share a room in the Medical Society building; we require our own office, which should be distinguished by its character and name.
- (2) We need also a permanent secretary, who would devote his whole time—an organizer, acting under the guidance of the honorary officers and committee, and assisted by an adequate clerical staff.
- (3) A complete reorganization of our honorary secretaries' list is needed. Personally I would hand over the collection of local subscriptions to the Divisions of the British Medical Association, for I am sure if the committee would co-operate in a more active manner with the Association greater support would be given and more money would be obtained. I do not share with Sir Charles Symonds his fear of the 20,000 non-members, and I would remind him they are a diminishing quantity, for the membership of the Association is annually increasing.
- (4) An annual dinner is, I think, very important. It should be carried out on similar lines to the "Artist's" Benevolent Fund dinner: well advertised and canvassed amongst the profession. A prominent public man should be asked to preside—the Prince of Wales as the first Chairman would be a splendid augury. He should be supported by a number of well chosen stewards, who would present to the treasurer their separate totals collected for him to read out at the dinner; this would stimulate competition to obtain the highest amount.

I am sure that if some alterations were made in the Benevolent Fund and would become better known and more largely supported. These reasons alone guided me in my criticisms at the Portsmouth meeting—I am, etc.,

G. B. HASLIP.

P.S.—The excellent new progressive idea of the Leicester Panel Committee, of subscribing a farthing for each State-insured patient, came either from Dr. Astley Clarke or from his committee, and not from any request of the Royal Committee of Management have thought of asking other Panel Committees to follow this fine example.

Sir—I have read with much interest all that has appeared recently in the Journal concerning the Royal Medical Benevolent Fund.

I am quite certain that in this, as in all other charities, fresh subscribers are only obtained by interest being aroused through the personal efforts of those who already subscribe. I would go so far as to say that all the promise that has been given by the doctors to the meagre support afforded by the profession generally will have little or no beneficial effect in securing an appreciable number of new supporters. The vast majority of readers will merely glance at the speeches and letters, and, while perhaps agreeing that such a fund deserves to be well supported, will think no more of the matter.

Two or three years ago I was appointed at my own request local honorary secretary for the Fund in the town in which I have practised for many years. I wrote to, or interviewed, every medical man and woman in the district, and with little or no trouble I obtained a subscription from every one without a single exception, thus being able to collect about £50. So far I am pleased to say, the subscriptions have been repeated annually, and I have no reason to believe that anyone intends to drop out. I take no praise to myself over this, for I am only doing my duty in a small way in trying to help those members of our profession and their dependants who have fallen on evil days. But what I want to emphasize is that what I have done plenty of others can do. I note that throughout England and Scotland there are only between 50 and 60 towns where organized collections take place under a local honorary secretary. It should not be difficult to get some members of the profession to act in this capacity in other towns as yet untapped, and I feel sure many doctors, if only asked, would be pleased to accept this position, thus ensuring increased personal service and interest all over the country.

I conclude with a practical suggestion. Scores of medical luncheons and dinners take place annually. An appeal on behalf of the Fund at these functions would, in my opinion, not be misplaced, and would always meet with a sympathetic reception. Many new subscribers would thereby be obtained and the amenities of the social gathering would be enhanced by the knowledge that a deserving charity had not been forgotten.

I render an account of my own stewardship annually at our medical dinner, and each year bring in a fresh subscriber or two, which encourages me to continue my self-imposed and pleasant task.—I am, etc.,

August 23rd.

ANTLERS AND BONE GROWTH.

Sir—I have just read the leading article upon Sir William Maclewen's address on "Antlers and Bone Growth" in your issue of July 21st.

Although I cannot lay claim to an extensive knowledge of the wide problems of human origin and variation, I have done my best to guard against the myopia but too readily induced by the contemplation of minute and specialized questions. I have, I trust, succeeded to the extent of being able to subscribe to your words:

"The doctrine he inculcates has a very important bearing not only on surgical pathology, but also on physiology and histological anatomy. Those who are working in the special fields of respective anatomy. (and as they hope) constituting surgery stand in need of the gentle reminders. They will show their worth by the manner in which they respond."

Every doctrine must be supported by sufficient evidence, otherwise it is no more than an expression of opinion. What is Sir William Maclewen's evidence, in so far as it concerns my own minute and specialized subject of histological anatomy? He has produced none, actual or theoretical, that the heterotopic bone in the pathological lesions he has described does not owe its existence to the activity of the fibroblasts of the granulation tissue in situ. Sir William Maclewen's "thousand memories of the atoms comprising each osteoblast" are merely a restatement in picturesque language of the fact that osteoblasts give rise to bone. They are based upon the assumption that a preformationist doctrine of development and growth is true. If we do not accept this doctrine they lose their meaning. I cannot see that Sir William Maclewen has brought forward

As was to be expected, prognosis in the elder patients was less good than in the younger, for the power of recuperation diminishes with age and osteo-arthritic changes are more prone to occur. Also as a rule the elder patients have been subjected to more numerous attacks.

By combining the two groups the results of operation were: Good, 35 cases (70 per cent.); fair, 11 cases (22 per cent.); poor, 4 cases (8 per cent.). Hence the prognosis is not by any means assured, but I believe these figures indicate a fair average of the results that may be expected if cases are "followed through" after operation. This is particularly necessary with internal derangements of the knee-joint, as cases apparently cured may relapse after a period of freedom. In one patient in this series who was apparently cured the condition suddenly recurred after an interval of nine months of strenuous life.

Prognosis should be especially guarded where attacks have been frequent and in the elderly. On the other hand, when once attacks have become established insecurity of the joint and osteo-arthritic changes are a natural sequence and may be diminished or controlled by removal of the offending cartilage.

## THE ANTISEPTIC ACTION OF THE STYRYL-PYRIDINES AND STYRYL-QUINOLINES.\*

BY

C. H. BROWNING, J. B. COHEN, S. ELLINGWORTH,  
AND R. GULBRANSEN.

(From the Organic Chemistry Department of the University, Leeds, and the Pathological Department of the University and Western Infirmary, Glasgow.)

THE formation of styryl-quinoline derivatives by the condensation, in presence of piperidine, of p-dimethylaminobenzaldehyde and quaternary salts of quinaldine and lepidine was noticed by König,<sup>4</sup> and, later, Barbier<sup>1</sup> and König and Treichel<sup>2</sup> described a number of substances of this type. Recently Mills and Pope<sup>3</sup> described the preparation of a similar kind of compound from  $\alpha$ -picoline methiodide, and also recorded the fact that this material, like the cyanines, possesses photosensitizing properties. The similarity in structure between these substances and those of the isocyanine type, together with observations made by us showing that the antiseptic potency of the isocyanines was increased by simplification of the quinoline portion of the molecule, suggested the possibility that the styryl compounds might also exhibit antiseptic activity. The relation between the two types will be apparent from the appended formulae:

### Preparation of the Styryl Compounds.

One molecule of p-dimethylamino-benzaldehyde and 1 molecule of the quinaldine methiodide were dissolved in alcohol, and the solution boiled for three to four hours after the addition of a small quantity of piperidine. The dyestuff, which crystallized on cooling, was in some cases recrystallized from alcohol. This further purification, however, did not increase the antiseptic potency.

These bodies have the advantage over the cyanines of being much more easily and rapidly prepared, and are obtained in much better yields. The following compounds were tested:

- 2 p-dimethylamino-styryl-pyridine methiodide;
- 2 p-dimethylamino-styryl-quinoline methiodide and ethiodide;
- 2 p-dimethylamino-styryl-6 aminoquinoline methiodide (base)
- 2 p-dimethylamino-styryl-6 methylquinoline methiodide and ethiodide;
- 2 p-dimethylamino-styryl-6 methoxyquinoline methiodide and the corresponding ethoxy compound;
- 2 p-dimethylamino-styryl-7 aminoquinoline methiodide hydrochloride.

Antiseptic properties were determined, as previously described.<sup>2,3</sup>

To 1 c.cm. of culture medium were added varying amounts of the substances to be tested along with 0.1 c.cm. of a 1 in 1,000 dilution in saline of a twenty-four-hour culture of the organisms (*Staphylococcus aureus* or *B. coli*) in peptone water. As test media (a) 0.7 per cent. peptone water with a pH value of about 7.2, and (b) undiluted ox serum (previously heated at 56° C.) were employed. The mixtures were then placed at 37° C., and were examined after forty-eight hours for the presence or absence of growth, which was determined in each instance by the appearance of turbidity in the fluid, and also by subculturing a loopful on agar.

In the case of *Staphylococcus aureus*, the sterilizing concentration of the above-named substances lay between 1 in 200,000 and 1 in 1,000,000 both in peptone water and in serum, except with 2 p-dimethylamino-styryl-pyridine methiodide, which was distinctly weaker (1 in 40,000 was required to produce sterility in both media). Toward *B. coli* the antiseptic action was never greater and usually somewhat weaker than toward *Staphylococcus*. For *B. coli* the most powerful compounds were 2 p-dimethylamino-styryl-6 methylquinoline methochloride and methiodide (sterilizing concentration in both media, 1 in 100,000 to 1 in 200,000). The occurrence of long zones of inhibition between concentrations which permit of active growth and those which sterilize completely is a feature of this group of compounds. In no case did the presence of serum cause a marked decrease in antiseptic power for either organism.

The toxicity of several compounds of the series was tested for mice; the tolerated dose was 1 c.cm. of 1 in 5,000 to 1 in 15,000 dilution for animals weighing 20 grams. Where lethal doses had been given there were no characteristic lesions in any organ.

The methochloride and methiodide of 2 p-dimethylamino-styryl-6 methylquinoline and the ethochloride and ethiodide of 2 p-dimethylamino-styryl-quinoline were tested on mice infected with *Tryp. brucei*; but with the maximal doses tolerated there was no effect on the course of the infection.

The chemical variations in the series involve merely alterations in side-chain substituents, apart from the pyridine compound. The substitution of a simple pyridine nucleus for a quinoline nucleus caused slight reduction of antiseptic power. Alterations in the side-chain occupying the 6- position are not very marked in their effect; the 7-amino derivative does not differ significantly in its action from those substituted in the 6- position.

Thus it is shown that substances belonging to the group of styryl-quinoline compounds are very powerful antiseptics.

A REPORT received by the United States Public Health Service at Washington shows a remarkable reduction in the infant mortality rate in Springfield and Campbell Townships, Green County, Missouri, since the establishment of a whole-time county health department. In 1918 the infant death rate in these two townships was 105 per 1,000. The county health department was organized that year. In the following year the infant death rate in the two townships dropped to 96 per 1,000. In 1920 it was 85, in 1921 it was 76, and in 1922 it was 61. This reduction of 42 per cent. in four years is regarded as a striking example of what may be accomplished in infant welfare by carrying out, with economy and efficiency, a well balanced general programme of health work affecting all age-sex groups in a community with a well administered health department under the direction of a whole-time health officer.

Obituary.

R. C. ACKLAND, C.B.E., M.R.C.S., L.D.S.,  
Dental Surgeon, St. Bartholomew's Hospital.

Mr. ROBERT CHAS. ACKLAND, who died on August 6th,

in 1866. His father died when he was quite young, and he

came of an old Devonshire family, and was born in Exeter

in 1809. He was educated at Exeter and Torquay, and after passing his preliminary

examination proceeded to London, entering at Charing

Cross Hospital and the Royal Dental Hospital, at the

former, in addition to the medal in anatomy, he obtained

distinction in several subjects. He took the L.D.S. Eng.

in 1837, and the M.R.C.S. and L.R.C.P. Lond. in 1839, and

settled in town. Soon afterwards he obtained the appoint-

ment of assistant dental surgeon to St. Bartholomew's

Hospital, and became senior dental surgeon many years ago.

During the war he was appointed medical officer in charge

of the Red Cross Hospital for Facial Injuries in Grosvenor

Square, and this, in addition to his large practice in Brook

Street, made inroads upon his strength, and his health

gave way under the strain. He received the C.B.E. for

his services. He was joint author of "Diseases of the

teeth" in *Quain's Dictionary of Medicine*, and wrote

several articles on dental surgery in textbooks and

periodicals. A splint he introduced for the treatment of

fractures of the lower jaw in 1833 is still largely used, and

was of great service during the war. He married a

daughter of Edmund Macarty, K.C., formerly treasurer of

the Middle Temple, by whom he had two daughters. The

large attendance at the Church of St. Bartholomew the

Great on the occasion of his funeral bore testimony to the

affection and regard in which he was held by his colleagues

and his many friends. His body was cremated at Golders

Green, and the ashes deposited in the churchyard over-

looking the sea at Winterton in Norfolk, close by his house

there.

R. C. Ackland was one of five brothers, all medical men

and all practising dental surgery. His brothers are J. M.

Ackland practising at Exeter, W. R. Ackland at Clifton,

C. H. Ackland at Bourne-mouth, and D. Ackland at Bath.

This record probably has no parallel.

We are indebted to Sir CHARLES GORDON-WATSON for the

following appreciation:

Ackland came to St. Bartholomew's Hospital in 1831 as

assistant dental surgeon after serving as demonstrator of

anatomy at Charing Cross. In these early days, when he

tought the dresser the art of extraction in most kindly

fashion, I made his acquaintance—an acquaintanceship

which ripened into a friendship of close on thirty years. It

was a very precious friendship, for he was a very lovable

man. Ackland possessed a magnetism, compounded of good

looks, boyish gaiety, and generous instincts. Modestly and

unobtrusively he was always doing somebody a good turn.

He served St. Bartholomew's for thirty-two years, and

there must be many Bart's men and many Bart's patients

who will lament his death. For he had that sympathetic

touch which attracted and endeared him to those with

whom he came into close contact. Ackland was at his very

best when entertaining at his house in Brook Street. His

friends loved to dine there; he was such good company,

such a good raconteur. In the outdoor life which he loved

are unconscious of their danger, and have no worry. Food should be fresh, and the ideal site is upon a farm where the medical superintendent can have charge of the milk supply.

The best air is that of the moors in September with a trace of frost in it. But damp and foggy air should be excluded, and only sufficient ventilation allowed to keep the atmosphere of the ward from becoming stuffy. If exposed to fog and damp, the patient has to fight both disease and environment, and the proper treatment of tuberculosis is none all the time. One of the best forms of rest in fresh air is a ride in a motor car on a dustless track, and some of the money spent on elaborate buildings might be better diverted to this form of treatment. Again, change of air is longer than six months at one sanatorium. If a dozen children's sanatoriums were established in different parts of England, and the children (that is, pulmonary cases) moved every three or six months, I believe that such changes of air would shorten the two years' cure by at least six months.

With regard to sunlight, I have previously pointed out in the *British Medical Journal* that it is the morning and the evening sunlight which is tonic, whilst the midday sun and air baths at the proper times—whilst the ward (verandahs) should run north and south, as this provides itself gives shelter (another important factor) from the midday heat. Shelter from wind is also essential, and the two verandahs give shelter from the east and west as is found desirable.

Given early diagnosis (and pulmonary diagnosis is the most important of anything in medicine or surgery) the above conditions would, I believe, give the best results in Nature's treatment of tuberculosis.—I am, etc.,

L. M. ALLISON.

Newcastle-upon-Tyne, Aug. 1923.

ETHER VERSUS CHLOROFORM.

Sir,—I have been reading the correspondence in your

columns, "Ether versus chloroform," with interest. I must

say I agree with Dr. Samways, and cannot understand why

chloroform is such a bugbear at home. During twenty

years' service in India I have never seen any deaths on

other general anaesthetic. I have never used, or seen used, any

has been given by dressers and compounders.

I have, however, had two deaths from delayed chloroform

poisoning; both of these were children from delayed chloroform

age to whom chloroform had been given for over two hours.

They were both cases of extensive tuberculous glands on

both sides of the neck, and I was tempted to do both sides

at once, as it is very difficult to get Indian patients to turn

up for a second operation.

I know that other medical men in this country will cor-

roborate my statements. Perhaps some will say that this is

due to the fact that in a hot climate the chloroform evapo-

rates quickly, and therefore the vapour is not so concen-

trated. Granted, but that does not apply to the cold

weather in the Punjab, where the climate approximates to

that of England, and is often in December and January

quite cold.

Personally I should never dream of using ether, not that

I have no experience of it, as I, when a house-surgeon at

Guy's, used it extensively; but open ether would be out of

the question in the hot weather; and the closed apparatus is

completely and cumbersome, and would rapidly become

unserviceable, as all rubber goods deteriorate rapidly in

this country. The only other anaesthetic I am using at

present is spinal anaesthesia, which I find very useful for

operations on the rectum, such as for haemorrhoids, where

full relaxation is required.—I am, etc.,

H. C. KEAYES, Lieut.-Col. I.M.S.,  
Ceylon Surgeon, Samarang, etc.,

perversion of the normal process; thus the number of cases capable of being damaged is nine times greater than if every case was left without interference." Though the construction of this sentence is open to criticism, its meaning is apparent, and it states a truth which, almost more than any other in practical obstetrics, requires emphasis at the present day. The remaining chapters are devoted to the different pathological conditions met with in pregnancy and labour. In regard to treatment, Dr. Fitzgibbon restricts himself to the methods which he personally employs at the Rotunda Hospital, and while this may simplify the matter for his students, it detracts from the value of the book to the more general reader, and prevents it from being regarded as a full discussion of the subject.

We turn with special interest to the chapter on pre-eclamptic toxæmia and eclampsia and find, as was to be expected, a very full, interesting, and detailed account of the method of treatment of this serious complication, which has been so successful in the hands of Dr. Fitzgibbon and his immediate predecessors, and is now being adopted alone, if for no other reason, the book is well worth possessing.

The dogmatic attitude, to which we have already referred, makes it inevitable that we should find ourselves at variance with Dr. Fitzgibbon in regard to some points of treatment. Thus, for example, it is disappointing to find him referring to manual rotation of the head in occipito-posterior positions in a very half-hearted sentence, which seems to suggest that any such attempt is foredoomed to failure. He devotes half a page to the extraction of the head by forceps as a face-to-pubes case, but to those familiar with the technique of manual rotation or rotation by forceps, delivery as a face-to-pubes case seems a confession of failure. Again, in discussing the mechanism of labour, Dr. Fitzgibbon states that "when labour sets in the vertical axis of the uterus shortens..." This is no doubt a slip due to insufficient revision, of which there are several other examples. Is not dogmatism carried rather too far when it is said that "When albumin is found in the urine of a case with any type of accidental hæmorrhage, the necessity of laparotomy as the only treatment must be accepted from the first, and the patient moved to suitable surroundings"?

Our object, however, is not to seek for faults in the book, and it is a pleasure to recognize this volume frankly as a useful contribution to the subject of practical obstetrics, and as a full statement of the methods which are at present the routine in one of the most famous maternity hospitals in the world.

### PREDISPOSING CAUSES OF PHTHISIS.

DR. PASSINI, director of the principal criminal sanatorium for tuberculosis in Italy, has published the first of a series of studies on some modern and important practical questions relative to diseases of the chest. His object is to make known certain deductions from his twenty years' experience, which he regards as indispensable to those who have not devoted their whole activity to the subject; and further to explain some personal views on the physiopathology of the disease. Mention is made of the symptoms that should lead the physician to suspect that a patient is the subject of tuberculosis. In addition to these, an examination for tuberculosis is, he considers, desirable when the symptoms of any of the following conditions are present: Hyperthyroidism, hypoadrenalism, the solar plexus syndrome and mucous entero-colitis, hypohepatism, pancreatic diabetes, and erythema nodosum. Pulmonary tubercle deviates frequently from its normal type, and a suspicion of its presence should arise when symptoms of the above-named diseases are present.

In describing the physical signs stress is laid on Baccelli's scapula sign (diminished mobility of the scapula on the diseased side) and on the presence of enlarged and tender glands in the axilla or neck, on one side of the body. In many cases the diagnosis is concerned with the activity or quiescence of the disease rather than its presence. The

presence of numerous bacilli in the sputum constitutes a presumption of activity, but is not decisive, since the extension of the disease may be limited by a barrier of fibrous tissue. Nor is the occurrence of hæmoptysis decisive, because a cirrhotic lung may give rise to hæmorrhage through occasional congestion. The temperature affords the most reliable evidence of quiescence; if during and after walking no rise of temperature occurs it may be assumed that the lesion is inactive, and even with a rise of temperature if this returns to the normal within an hour quiescence is probable.

The author has no doubt that pulmonary tuberculosis is curable in the anatomical sense. Autopsies show that tubercle is commoner than was supposed, that it may have an absolutely latent course and undergo spontaneous cure, and that the cases usually seen probably represent the graver and less curable forms. Dr. Passini considers that it is legitimate to speak of a pretuberculous stage—that is to say, a stage of incubation—and he enumerates its signs and symptoms. Two chapters are devoted to the relation of hepatism and the circulation to tuberculosis. It is held that hepatic insufficiency in its milder degrees is an indirect cause of tuberculosis, and that successful treatment of the condition may in some cases ward off tubercle in its earliest stage.

### THE GROWTH OF CELLS.

IN a monograph<sup>4</sup> issued from the Institute of Physiology of the Faculty of Medicine of Strasbourg, MM. E. LE BRETON and G. SCHAEFFER have attacked the problem of the growth of cells along biochemical lines, and have studied the relation between the total nitrogen and the purin nitrogen content of embryos during the first few weeks of development. The variations between the size of the nucleus and the size of the cell during early embryonic development have been studied by several morphologists, but, as the authors point out, a morphologist is confined to two dimensions in such studies, and therefore the biochemical line of investigation offers obvious advantages. The book commences with a history of the various investigations which have been made to determine what proportion of an animal's tissues consists of living protoplasm and what proportion serves merely as a food store. The study of starving animals has yielded remarkable results in this connexion, and Rübner has concluded that in addition to the food stores of fats and carbohydrates, about half of the protoplasm of cells can also act as a food store. In a starving animal about half the protoplasm of the cells can be removed without the destruction of the cells. Special attention has been given to muscle cells, and it has been shown that though in starvation the muscles undergo enormous wasting, there is no destruction of any of the muscle fibres. Measurements of the muscle cells have shown that in a starving animal the individual muscle cells may be reduced to as little as one-fourteenth of the volume of the muscle cells of a fat animal. These and other facts are adduced to establish the clear distinction that exists between that portion of cell protoplasm which is essential to cell life, and the remaining protoplasm or paraplastm.

The nucleus is the most important part of the essential protoplasm, and the authors have measured the purin content of tissues to get an indication of the mass of nuclear material; the total nitrogen less the purin nitrogen is taken to indicate the mass of non-nuclear protoplasm.

The authors of the monograph now before us used hen's eggs, pig embryos, and mouse embryos, and made in each case estimations of the relation between the mass of nuclear material and mass of non-nuclear protoplasm during the first few weeks of development. From the figures thus obtained they have produced curves showing the variations in the ratio, and also the rate of increase of the various substances estimated. Their chief conclusions are that during the course of foetal development the ratio of mass of nucleus to mass of cytoplasm decreases steadily and the rate of decrease follows a regular curve. The rate of decrease is

Recherches de physiologie générale sur la détermination de la masse protoplasmique active. Paris: Masson et Cie. 1923. (Roy. 8vo, pp. 177; 15 figures. Fr. 15.)

# Universities and Colleges.

## UNIVERSITY OF CAMBRIDGE.

In accordance with a Grace approved by the Senate on June 8th, 1923, confirming a report of the Special Board for Medicine, important changes in the regulations for medical and surgical degrees will come into force in October next. Copies of the regulations and schedules may be obtained from the Registrar of the University. The main features of the new regulations will be noted in the section on the University of Cambridge in the annual Educational Number of the British Medical Journal, published next week.

The following candidates have been approved at the examination indicated:

*Diploma in Tropical Medicine and Hygiene*—R. A. Anderson, J. M. Gosh, M. E. Greenham, K. K. Shennel, J. H. Spencer, K. S. Thakur, F. C. Thompson.

## UNIVERSITY OF LONDON.

### UNIVERSITY COLLEGE.

The Diploma Scholarship held in the Faculty of Medical Sciences has been awarded to Mr. G. G. Gilliam.

## The Services.

### MEDICAL DIRECTOR-GENERAL, R.N.

Surgeon Rear-Admiral Joseph Chalmers, C.B., C.M.G., has been selected for the post of Medical Director-General, R.N., and will take up office on October 1st. He is succeeded as officer in charge of the Royal Naval Hospital, Plymouth, by Surgeon Rear-Admiral Arthur Gaskell, C.B., O.B.E.

### R.C.V.O.

The King has been pleased to promote Surgeon Captain A. R. Babcock, C.V.O., R.N., to be a Knight Commander of the Royal Victorian Order.

### DEATHS IN THE SERVICES.

Lieut.-Colonel James Edward Carter, R.A.M.C. (retired), died of epileptic poisoning at Metchinville, North Wales, on July 27th, aged 55. He was born at Longshilly, Armagh, on April 25th, 1868, the son of the late Rev. H. B. Carter, D.D., of Derrytown, Co. Down, where he was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A. in 1889; he took the D.P.H. in 1902. Entering the army as surgeon on January 31st, 1901, he became major on December 2nd, 1903, and retired on December 2nd, 1913. He was recalled to the active list for service in the late war on August 5th, 1914, and promoted to lieutenant-colonel on May 25th, 1919. He also served in the South African war in the actions at Modder River and Magersfontein, and in the operations in the Orange Free State, including the ten-day action of Paardeberg, February 17th to 23th, 1900, in which he was severely wounded, and received the Queen's medal with two clasps.

Major William Macdonnell Macdonnell, R.A.M.C., died suddenly at Middlesbrough, Yorkshire, on board the British India s.s. *Manila*, on June 22nd, aged 51. He was the only son of James Macdonnell, Esq., of Clonach, and was educated at the London Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. After serving as surgeon on the Naval Direct Force of steamers, and as assistant medical officer at Hoxton House, London, in 1901, he served as surgeon on M.R.C.S. and L.R.C.P. Assisting, he entered the R.A.M.C. as lieutenant on August 5th, 1903, and became major on February 28th, 1916. He served in the recent Great War, and acted as lieutenant-colonel from April, 1917, to August, 1919.

## Medical Notes.

The annual Westminster Hospital old students' dinner will be held on Thursday, October 4th, at the Empire Rooms, Trenchard Restaurant, Piccadilly, W. Mr. W. G. Spencer will be in the chair. The honorary secretary is Dr. Adolphe Abraham, 17, Harley Street.

Professor Ciro Caldera has been appointed to the chair of ophthalmology in the University of Pavia.

Post-graduate courses on dermatology and venereal diseases will be held in Pavia at the museum of the St. Louis Hospital and the amphitheatre of the Clinic, 40, Rue Bichat; the course on dermatology will commence on October 5th, and that on venereology on November 14th. The courses will be conducted under the direction of Professor Ganselme, Dr. Sabouraud, and others. The fee for each course is 150 francs.

The Spanish Congress of Pediatrics will be held at San Sebastian from September 2nd to 7th, under the presidency of Dr. Arguedas.

A detailed programme will be sent on request.

The *Journal of Tropical Medicine and Hygiene*, J. M. Gosh, M. E. Greenham, K. K. Shennel, J. H. Spencer, K. S. Thakur, F. C. Thompson.

The famous histologist, Professor Camillo Golgi of Pavia, has recently celebrated his 80th birthday.

The twenty-ninth congress of the Italian Society of Internal Medicine will be held in Rome, under the presidency of Professor V. Ascoli, from October 24th to 26th, when the following subjects will be discussed: (1) Diabetes insipidus, introduced by Professor Ascoli Mantovani; (2) cholera, introduced by Professor Saverio Forcino; (3) pro-gress in diagnosis and treatment of heart diseases, introduced by Professor Baracco Amerigo; Further information can be obtained from the secretary of the congress, Professor Giuseppe Sabatini, Clinica Medica, Policlinico Umberto I, Rome.

The Board of Trade's reference has ruled that formaldehyde should be excluded from the list of articles chargeable with duty under Part I of the Safeguarding of Industries Act.

The thirtieth congress of the Italian Society of Surgery will be held in Rome from October 24th to 26th, when the following subjects will be discussed: (1) Infections of the gall bladder, with special reference to pancreatitis, introduced by Professor Muscarello; (2) Infections of the large bile ducts, introduced by Professor Crosti; (3) Grating in general, including skin grafts, introduced by Professor Pastano; (4) Nerve grafts, introduced by Professor Chissarini. Further information can be obtained from the secretary of the congress, Professor Leonardo Dominici, Clinica Chirurgica, Policlinico Umberto I, Rome.

The Health Commissioner of Chicago has refused to license a parents' clinic for the purpose of giving information concerning the control of conception. The mayor, on appeal, refused to interfere with the Health Commissioner's decision, and the whole question has been submitted to the corporation council for a legal opinion.

The second congress of the Italian Society of Urology will be held in Rome on October 27th, when the following subjects will be discussed: (1) Functional examination of the kidneys, introduced by Professors Piriondi and Raimondi; (2) Iodothyrotherapy in urology, introduced by Professors Busi and Bonamonte; (3) Radiotherapy in urology, in co-operation with the Health Commissioner of Chicago has refused to license a parents' clinic for the purpose of giving information concerning the control of conception. The mayor, on appeal, refused to interfere with the Health Commissioner's decision, and the whole question has been submitted to the corporation council for a legal opinion.

The third annual report on the work of the Shanghai Public Health Department for 1922 Dr. C. Noel Davis, Commissioner of Public Health, records that the outbreak of small-pox which started in 1921 continued until the following April. The campaign of vaccination was carried on with great vigour, and the effect began to be seen early in the year, when the outbreak waned, and only a few sporadic cases occurred after the end of March.

A report on plague in Egypt during the year 1922 has been issued by the Department of Public Health of the Ministry of the Interior. The total number of cases of plague was 497, including 25 foreigners; the deaths numbered 228, including those of 15 foreigners. The cases and deaths were distributed fairly evenly between Lower Egypt and Upper Egypt.

The eleventh annual report of the medical department of the United Fruit Company, issued from the general office of the company at Boston, Massachusetts, is a sumptuous publication of nearly 150 pages. In the course of his introductory letter Dr. W. E. Deeks records that in August, 1922, the United Fruit Company inaugurated a free medical wireless service and consultation with its hospitals and steamships and all ships at sea. The announcement of this service was translated into French, Spanish, and Portuguese, and was distributed to merchant shipping throughout the world. It was established primarily for the benefit of ships not carrying doctors; but ship's surgeons may consult by wireless with the company's doctors, either aboard ship or ashore. Radiograms requesting medical advice have a special code prefix, and are given preference over all other messages except SOS calls through the wireless service of the United Fruit Company and its subsidiary companies.

The *Journal of Tropical Medicine and Hygiene*, J. M. Gosh, M. E. Greenham, K. K. Shennel, J. H. Spencer, K. S. Thakur, F. C. Thompson.

The famous histologist, Professor Camillo Golgi of Pavia, has recently celebrated his 80th birthday.

results of much personal research. A welcome feature is the space devoted to the comparative pathology of malignant disease in animals.

### ST. BARTHOLOMEW'S HOSPITAL REPORTS.

THE second part of this year's volume of *St. Bartholomew's Hospital Reports*<sup>\*</sup> opens with an admirable and sympathetic obituary notice of the late Sir Norman Moore, illustrated by a full-page portrait of the late President of the Royal College of Physicians. Dr. Ormerod, his colleague both at the hospital and at the College of Physicians, writes with personal touches drawn from their many years of companionship. He mentions that if Moore thought the patient (or others) too curious about the diagnosis of a case in the wards it was written at the head of the notes in Irish; as teacher and lecturer Sir Norman Moore attracted students by making even the most commonplace cases interesting. Full justice is here done to the learning, wit, and versatility of "a man singularly responsive to all human interests." Mr. Girling Ball contributes a good account of diverticulum of the urinary bladder based on two cases without any obstruction to the outflow from the bladder, which were successfully treated by radical surgical measures; he concludes that whether associated or not with obstructive lesions in the bladder and urethra the origin is the same—namely, some defect in the bladder wall, either a gap in the musculature or a deformity resulting from the persistence of a portion of the urachus or an accessory ureteric bud. Acetonuria and its relation to surgical operations was investigated by Mr. G. H. Caiger in 76 cases, of which about 40 per cent. had post-operative acetonuria, sex having no influence. From these cases and from observations on himself he finds that diet is the only important factor. The remainder of the volume is devoted to a series of lectures given in the winter session on syphilis from different aspects. Its history from the earliest times to the present day is sketched with his usual charm by Sir D'Arcy Power. Mr. John Adams draws on his experience at Thavies Inn Clinic for his account of the ante-natal and post-natal disease, and Dr. Branson deals in a temperate manner with its bearing on life assurance. The nervous lesions are described by Dr. Hinds Howell, and Colonel L. W. Harrison has contributed from his experience his views on prevention.

### NOTES ON BOOKS.

F. FRANÇON and J. HUTINEL's monograph *Les hépatites amébiques, autochtones et coloniales*<sup>†</sup> was inspired by their teacher, Professor Chauffard, who contributes a short preface, and by their war experience in Morocco and with the Second Army. The occurrence of amoebiasis in France among people who had never been abroad was recognized before 1914, but became more noticeable after the war. This monograph is rich in references to the work of others and full justice is done to British writers and especially to Sir Leonard Rogers. After a brief sketch of the history of amoebiasis since the *Entamoeba histolytica* was discovered, the various forms of amoebic hepatitis are tabulated and described—namely, pure and mixed infection, such as with bacillary dysentery, malaria, and tuberculosis; acute, sub-acute, and chronic inflammation and suppuration. The predominating influence of emetine on the clinical picture, prognosis, and treatment is forcibly brought out, and it is well said that the prognosis of amoebiasis depends on its diagnosis. It is remarkable how rare it is, even with Vidal's haemoclastic test, to find evidence of hepatic insufficiency in amoebic hepatitis. The indications for surgical intervention and for medical treatment are given, and of the three forms of medical treatment—emetine alone, 914 alone, or these two combined ("ENV")—the last is said to be that now in popular favour. The toxic effects of these remedies are wisely pointed out, and the causes of failure of emetine in certain cases are discussed. This compact little work contains a great deal of recent information and will serve as a useful source of reference.

<sup>†</sup> *Les hépatites amébiques, autochtones et coloniales et leur traitement*. Par F. Françon et J. Hutinel. Paris: Gauthier-Villars et Cie. 1923. (Roy. 8vo, pp. 131. Fr. 10.)

Mrs. GASQUOINE HARTLEY's little book on *The Mind of the Naughty Child*<sup>‡</sup> is the fifth volume of a series entitled "The Blue Booklets," which consist of "plain talks on vital topics of the day." In very simple language the author, who is obviously permeated with Freud's doctrines, discusses the causes underlying the various forms of naughtiness in children, dealing successively with the bumptious, boastful, and violent-tempered child, the sulky child, the jealous child, the destructive child, the inquisitive child, and the lying child. The book will interest parents.

With the holiday season in full swing what better time could there be for the appearance of Mr. G. R. STIRLING TAYLOR's *Oxford: A Guide to its History and Buildings*,<sup>§</sup> for they cannot stay there for three or more years require some kindly help in getting to know the spirit of the place? Of guides there are several kinds; some are full of accurate dates and details, while a few, wisely casting aside all pretence at omniscience, tell the story with the happy knack of exciting appetite for more. Of this more excellent type Andrew Lang's *Oxford: Brief Historical and Descriptive Notes* was a good example, and Mr. Stirling Taylor's book follows the attractive lead in giving as the first of its three parts the outlines of the history which the reader is advised to study before setting out on his voyage of sight-seeing. The second part—an itinerary of Oxford in historical order—is to be read *en route* with reference to the notes and illustrations contained in part three. The illustrations are admirably produced and the comparatively low price of this attractive handbook is noteworthy.

<sup>‡</sup> *The Mind of the Naughty Child*. By Mrs. Gasquoine Hartley. London: A. M. Philpot, Ltd. 1923. (Cr. 8vo, pp. 30. 2s. 6d. net.)  
<sup>§</sup> *Oxford: A Guide to its History and Buildings*. By G. R. Stirling Taylor. London: Longmans, Green, and Co. 1923. (Cr. 8vo, pp. 125; 25 plates, 1 map. 4s.)

### APPLIANCES AND PREPARATIONS.

*Card Index System of Book-keeping and Case-taking.*  
WE have received from Messrs. H. K. Lewis and Co., Ltd., 136, Gower Street, W.C.1, particulars of their card index system with specimen cards. These are four in number—an account card, a case card, a plain card for continuations, and a temperature card. The account card is ruled for twelve months of thirty-one days with a series of three money columns following, and a column for the date on which the account was sent. It can thus be made to serve both as day-book and ledger. At the head of the case card are spaces for the name and address of the patient, and particulars as to age, sex, married state, occupation, and date. The rest of the card is plain. The temperature card is of the ordinary chart type, with both Fahrenheit and Centigrade scales indicated. All the cards are of the same size—the same width as an insurance record card and about an inch longer—8 in. by 5 in. Card index systems are in increasing use, and this is a particularly convenient and useful one for the methodical practitioner who is at the same time busy and careful. A cabinet is supplied for holding the cards; they can be perforated for use also in a holder, the cards for the day's round, if wanted, being taken from the drawer and placed in the holder and put back at the end of the day. The cards are of suitable thickness and surface for easy writing, and the prices appear reasonable. Messrs. Lewis state that specimens will be sent to any medical practitioner on application.

#### *A Protein-Iron Preparation.*

Messrs. E. T. Pearson and Co., Ltd., have produced from edestin a compound for medicinal use containing 10 per cent. of iron in the ferric state, which is sold under the name of "Protoferrin Brand Organic Iron." Edestin is a vegetable protein occurring plentifully in the seeds of flax, hemp, and cotton, and is manufactured by Messrs. E. T. Pearson for use as an accessory to the diet of mothers during lactation. It belongs to the group of proteins characterized by solubility in water containing about 15 per cent. of ammonium sulphate and by insolubility in water saturated with the same salt. It is also soluble in a solution of sodium chloride. The chemical union of iron with a digestible protein offers an interesting subject for study in therapeutics. It is contended that the exhibition of iron in this form gives all the advantages to be derived from treatment with iron, without the risk of the astringent action and constipative effect experienced with ordinary iron compounds. An analysis made at our direction has verified the correctness of the constitution ascribed to Protoferrin Brand Organic Iron, and physiological tests are also reported to have been made with satisfactory results. This compound may prove to be a very useful addition to the resources of prescribers.

**Typhoid Perforation of the Intestines.**

J. SANDHUS (Leningrad) has found from a study of Finnish statistics that the incidence of typhoid perforation of the gut is considerably greater in men than in women. In 1890, 18 women and 35 men have suffered from this complication of typhoid fever since 1857, and at the author's hospital and another hospital in Helsinki 25 men and only 8 women have been treated for this condition during the past twenty years. Why it should show such predilection for men is not clear. Of a total of 55 cases operated on in Finland for typhoid perforation, only 7 terminated in recovery, and this low recovery rate of 12.7 per cent. must be traced to the fact that most cases come to operation at a comparatively late stage. The author records in detail the case of a workman's wife, aged 40, whose appendix became glued to the perforation in the intestine, sealing it up, and thus saving her from severe peritonitis perforation from the escape of the intestinal contents into the peritoneal cavity. This patient recovered.

**150. Recurrence of Gall Stones after Cholecystotomy.**

A. GOSSET (Bull. et Mem. Soc. Chir. de Paris, April 24th, 1923, p. 555) points out that the so-called operation of "ideal cholecystomy" was first performed in 1853. This operation is now only mentioned in textbooks of surgery to be condemned. This procedure was advocated in cases where the gall bladder was healthy with thin walls, and in cases where the cystic duct was permeable and of normal calibre and in the absence of signs of infection. The author has recently had under his care a patient with gall stones, who had the conservative operation of cholecystotomy performed in 1910. For thirteen years the patient had rejected attacks removed from the gall bladder. In 1923 the gall stones were removed for a recurrence of the gall stones. A transverse scar across the fundus of the gall bladder could be recognized, the result of the previous operation. Histological examination revealed absence of the mucous membrane in the line of the scar. This case demonstrates that only removal of the gall bladder is able to prevent recurrence of gall stones, and it convinces the author that, notwithstanding recent assertions to the contrary, cholecystotomy is not the ideal operation.

**Ophthalmology.**

**151. The Treatment of Conical Cornea.**

C. KILICK (Brit. Journ. Ophthalmol., June, 1923, p. 264) discusses the treatment of conical cornea. After a brief summary of the pathology of the condition he describes his experience with regard to treatment. In his earlier cases he has tried sclerotomy, cauterization, with and without perforation of the cornea, and the performance of the first stage of a cataract extraction, making a large flap and maintaining a pressure bandage for some time afterwards. The experiences he has had with all these procedures, and in fact obtained better results by the non-operative method of pressure bandage, and rest. Recently he has dealt with a case by operation, and has obtained a much more favourable result. The method he employed in this instance was as follows: He first excised the lens in the ordinary manner. As the lens was only slightly cataractous there was a considerable amount of after-cataract remaining; in needling this he made an incision in the capsule 1 mm. broad and 1.5 cm. long in the vertical diameter, establishing therefore a narrow slit. This incision was based on the well established fact that vision in conical cornea is improved by narrowing the pupil or by making it resemble a stenopæic slit. Before operation this patient had approximately 32 dioptres of myopia, and after operation with — 5 D. sphere the vision was improved to 6.74.

**152. Neurotic Disturbances of Eye Function.**

L. K. LUTY and A. F. RIGGS (Arch. of Ophthalmol., July, 1923, p. 313) deal with those cases, so commonly met with, of slight refractive error with marked symptoms who do not get the expected benefit from glasses. The following case is quoted as typical. An intelligent woman of 50, with a family history of "weak eyes," has never been anything but on the other hand there has never been anything definitely wrong with her. She has always been rather shy and reserved, not making friends very readily. She has been happily married for twenty-five years, but owing to a pelvic condition has never had any children; this has disappointed her greatly. Her husband is of a somewhat neurotic temperament. Eight years ago she had an attack of typhoid fever, since when she has never been able to use her eyes with comfort. This state of affairs has gone from bad to worse

**Obstetrics and Gynaecology.**

**153. Extrauterine Pregnancy at or near Term.**

H. E. HAY (Amer. Journ. Gyn. and Obstet., June, 1923, p. 601), having encountered two cases of extrauterine pregnancy near term fall time, summarizes various points of interest connected with this rare condition. The author shows that the diagnosis is extremely difficult as pregnancy progresses apparently normally, there being no signs of violent rupture and no loss of blood in the early months to draw the patient's attention to some abnormality. When examined near term the textbook descriptions, which usually state that the local heart sounds are usually loud and the lungs easily felt, were not found to be the case, nor was the child found to be more on one side of the abdomen than the other. The cervix, however, was much harder than in a normal pregnancy near term, and in both cases the uterus could be felt per vaginam as a hard mass below the pregnant sac, which caused the diagnosis of a broad ligamentary pregnancy to be made in each. The symptom which caused both patients to seek medical advice was a sudden obstruction of the bowels due to adhesions of the sac.

**154. Treatment of Xanthoma Palpebrarum with Finest Light.**

S. LOHMOLT (Ugeskrift for Læger, May 31st, 1923, p. 350) notes that as xanthoma palpebrarum is a perfectly benign and painless growth, doctors are seldom called on to treat it, although in his experience it is a very common condition. From the cosmetic point of view, however, it is a serious condition, and at the Finson Institute in Copenhagen the usual practice adopted in these cases up to the spring of 1922 has been to give radium treatment. But this treatment proved tedious, and better results have recently been achieved with concentrated carbon arc light applied in the same way as for lupus. A single exposure of about one hour was in some cases repeated three or four times, a certain interval being allowed between each exposure for the reaction to subside. At the Finson Institute 11 cases have recently been treated in this manner, and the results have been very good. The yellow patches disappeared completely, or almost so, and without the formation of any scar. Only in a few cases was there a slight pigmentation left in the periphery of the area treated, and it should be noted that such pigmentation may exist before treatment. Provided the first course of treatment is adequate, there seems little chance of relapses in this, but this treatment does not, of course, prevent recurrence of the disease in new areas. The author considers that even in the tuberculous form of the disease, Finson light is superior to any other form of treatment.

**155. Ocular Complication following Abortion.**

J. PESKE and D. VAKANGZ (Gaz. hebdom. des sciences med. Bordeaux, March 18th, 1923, p. 123) record the case of a woman, aged 19, who, eleven days after a two months' abortion, complicated by digital removal of a portion of the ovum, became suddenly blind in one eye, which showed a preretinal haemorrhage in the region of the macula. The abortion had been attended with considerable loss of blood, and the patient suffered from uterine stasis. Discussing the cause of the ocular haemorrhage the authors exclude both the ordinary post-haemorrhagic lesion which is characterized by oedema of the papilla and is bilateral, and the recurring haemorrhage of adnexa, which quickly invades the vitreous; the blindness followed the first effort of the patient to sit up, and is ascribed to sudden augmented tension in a condition of lowered intra-ocular pressure. Seven weeks later visual acuity had been restored to 5/10.

and she eventually could only use her eyes for a few minutes at a time. She even contemplated learning Braille. She had consulted at various times competent ophthalmic surgeons, who one and all had assured her that beyond a very small error of refraction, for which glasses were prescribed, there was nothing wrong with her eyes. She had a genuine desire to get well, and after eight weeks of graduated eye exercises was able to use her eyes in concentrated efforts for three and a half hours a day. The author points out that this type of case requires more than the fitting of glasses. Re-education of the faculty of sight is necessary. In the process of re-education each case must be approached individually and with great sympathy. Graduated reading exercises must be indicated, the length of the daily exercise being gradually increased, but great care being taken not to advance too quickly. Finally, there must be careful oversight of the physical activities as well as the training of the suppositively handicapped function, so that the gains may become real and permanent.

concluding high note of friendship for France so moved the audience in the theatre of the Sorbonne that the Minister of the Interior left his presidential chair and cordially shook the hand of the speaker amidst great applause.

During the meeting the Miller Memorial Prize, which consists of a gold medal, an illuminated diploma, and a sum of money, was presented to Mr. J. Howard Mummery for his distinguished work in dental histology. In the various commissions, or sectional meetings of the Federation, held during the week progress was made in attempts to arrive at a universal ideal curriculum for dental studies, and a collective investigation into the best means of carrying out public dental service on the most economical basis was also begun. Professor Jensen incidentally referred to a cheap metal plate for a denture which was now in use amongst the many thousands employed in Krupp's factories at Essen. A specimen plate, which he showed, had the appearance of platinum but consisted of very thin stainless steel; five years' use had shown it to be practically unbreakable, and it was not acted upon deleteriously by the oral fluids. Unfortunately, from the professional point of view, the makers of the metal, who were Messrs. Krupp, had refused to divulge the secret of its manufacture. The collection and the documentation of all published matters relating to dentistry, either scientific or general, were proceeding under the skilled guidance of Dr. Huet at the great library of bibliography in Brussels, and it was hoped that at some future date the result would be an important work of reference. A visit to the tomb of Dr. Charles Edouard Godon in the cemetery of Père Lachaise, Paris, one of the founders and an honorary president of the International Dental Federation, who died recently, was made by a delegation of the Federation.

During the meeting various ceremonial functions and entertainments were organized by the French members of the Federation. The meeting terminated in a pleasant excursion by motor car to the country home, near Versailles, of Pierre Fauchard, "the father of French dentistry," who died in 1786.

## Nova et Vetera.

### TAR WATER.

If we are a nation of shopkeepers, none of us minds his own shop with an exclusive devotion; the triumphs of the amateur are the glories of England. Charles Darwin was not a professor, George Boole taught himself mathematics, John Dalton was self-educated. These names illustrate the successes of the amateur; his failures are sometimes instructive, and the history of medicine provides many examples. The story of Tar Water is a case in point. In 1744 there was published *A Chain of Philosophical Reflexions and Inquiries concerning the Virtues of Tar Water and divers other Subjects connected together and arising one from another*. It was reprinted the same year with additions and a new title, *Siris* (from *σειρά*, a chain), and reached a fifth edition by 1748. "We are now," said Horace Walpole, "mad about the water, on the publication of a book written by Dr. Berkeley, Bishop of Cloyne. The book contains every subject from tar water to the Trinity; however, all the women read it and understand it no more than if it were intelligible. A man came into an apothecary's shop the other day: 'Do you sell tar water?' 'Tar water?' replied the apothecary, 'why, I sell nothing else!'"

Our profession vigorously denounced the "epidemic madness of drinking tar water," thus, as some cynics held, justifying Berkeley's claims. But the cynics were wrong; all that remains of tar water in the memory of man is covered by a phrase. "The luminous spirit," said Berkeley, "lodged and detained in the native balsam of pines and firs is of a nature so mild, and benign, and proportioned to the human constitution as to warm without heating, to cheer but not inebriate." Cowper applied the last phrase to tea and made it immortal, the one unruined link of Berkeley's chain.

What did Berkeley claim for tar water, and why? As to the first question it would be hard to say what he did not claim. To begin, it was a sure prophylactic against small-pox. He knew a family of seven, all of whom escaped "except one young child which could not be brought to drink tar water as the rest had done," while Captain Drape of Liverpool made a solemn affidavit that of "170 negroes seized at once by the small-pox on the coast of Guinea one only died, who refused to drink tar water; and the remaining 169 all recovered, by drinking it, without any other medicine, notwithstanding the heat of the climate, and the incommodities of the vessel" (*Second Letter to Thomas Prior*, par. 18). Tar water was sovereign in cutaneous eruptions and ulcers—"encouraged by these successes I ventured to advise it in the foulest distempers, wherein it proved much more successful than salivations and wood drinks had done." Tar water was also very good for gout, but "nothing is more difficult or disagreeable than to argue men out of their prejudices; I shall not therefore enter into controversies on this subject, but if men dispute and object, shall leave the decision to time and trial."

If it be objected that one and the same medicine cannot possibly cure so many different diseases, we should remember that opposite causes sometimes produce the same effect: "it is not therefore strange that tar water should warm one habit and cool another, have one good effect on a cold constitution, and another good effect on an inflamed one; nor, if this be so, that it should cure opposite disorders."

How did it come about that one of the acutest thinkers of the eighteenth century, familiar—as *Siris* itself proves—with the Hippocratic collection, reasoned so ill? Part of the explanation is that although Berkeley was a fine reasoner, his field was remarkably narrow. Hardly anyone since Plato has been acuter in the use of dialectic, hardly anyone of equal powers has been so destitute of either mathematical or experimental tact. His *Analyst* exhibits a total failure to comprehend the leading ideas of Newton's doctrine of fluxions—of what we now call the infinitesimal calculus; Jurin, who although eminent in both mathematics and physic was a much smaller man than Berkeley, easily vanquished him in the mathematical controversy. A fraction of the skill with which Berkeley dissected the notion of "matter" would have made short work of Captain Drape's solemn affidavit.

But this cannot be the whole explanation. Practical economics are at least as far from dialectics as practical therapeutics, and Berkeley was a much better practical economist than most of his contemporaries, as a few extracts from the *Querist* will prove, thus:

"Whether the women may not sew, spin, weave, embroider, sufficiently for the embellishment of their persons, and even enough to raise envy in each other, without being beholden to foreign countries?"

"Whether, if drunkenness be a necessary evil, men may not as well get drunk with the growth of their own country?"

"Whether it must not be ruinous for a nation to sit down to game, be it with silver or paper?"

We should suppose the cause of his failure to lie deeper; to be what it is now fashionable to call a "complex," which certainly sounds much wiser than *arrière pensée*. Berkeley's "complex" was a conscious and unconscious wish to smother the "deists." This prompted his successful onslaught on "matter" and his unsuccessful attack on fluxions. He was no doubt worried because, as Lord Balfour said, "ordinary men were not prepared to admit that a Deity was necessary because matter was impossible." If he could but discover a panacea, his argument for Divine Providence would be clinched. Tar water was that panacea, and proof of its efficiency no more than rationalizations—to adopt another fashionable term for what used to be called argumentation *ex post facto*.

Here perhaps we have the explanation of many other panaceas before and after Berkeley's time, from the elixir of Paracelsus to the *Bacillus bulgaricus*. The physician must be a philosopher, but a simpler philosophy than that of Berkeley may serve his turn better—that of the worldling who said:

"Virtus est vitium fugere, et sapientia prima Stultitia caruisse."

CHIEF MEDICAL OFFICER, BOARD OF EDUCATION AND MINISTRY OF HEALTH.

THE VICTORIES OF PREVENTIVE MEDICINE.

Tuberculosis is a third example. In 1877 the death rate above one per cent reached the stage of alarming importance. It has steadily declined for seventy years and in 1921 it was 854. Non-pulmonary tuberculosis is likewise declining. If the disease be as widely distributed as is generally supposed, it must indeed be one of the most curable of the great scourges. What is the explanation of its decline? The answer is prevention. An improved milk supply, institutional treatment of the disease, better nutrition, sanitation of the home and the workplace, the reduction in the habit of promiscuous spitting, and an immense advance in social well-being are, in spite of voluble and inconstant

## THE HEALTH AND THE INTELLIGENCE AND PHYSIQUE OF SCHOOL CHILDREN.

PROFESSOR KARL PEARSON has many titles to respect, amongst them his prowess as an iconoclast. A secondary definition of the word "iconoclast" is one who assaults or attacks cherished beliefs. Even the first iconoclasts of the eighth and ninth centuries did not manage to break all the idols, any more than the Protestants of the sixteenth and seventeenth centuries succeeded in smashing all the images on our churches. Professor Karl Pearson will perhaps be no more successful than his predecessors, but students of medicine and sociology are sincerely grateful to him for now and again asking them to examine critically the grounds of their confident beliefs. The most recent publication of the Galton Laboratory deals with the relationship of health to the psychical and physical characteristics of school children,<sup>1</sup> and is based on information collected between 1898 and 1903 from teachers in a number of secondary and elementary schools. The teachers recorded the measurements of a number of quantitatively defined characters and classified a number of non-measurable characters. The classification of intelligence was based upon a very careful series of definitions of categories supplied by Professor Pearson. A large number of pupils—2,388 boys and 2,290 girls—were examined.

Many of the results deducible from this valuable collection of data have already been published by Professor Pearson, notably in his Huxley Lecture. With regard to the interrelationship of health and psychical or physical characters, he concludes in the first place that there is little or no change either in health or intelligence through school life. Indeed, "vivacity" in boys and "popularity" and handwriting in girls are the only characters furnishing a correlation with growth which exceeds 0.1, the sign in each instance being negative.

Passing to the correlations of the estimate of health with other estimates and measurements, the results are these. The correlation is greater than 0.2 in three instances—with athletic power (0.443), with self-assertion (0.263), with vivacity (0.222). It is between 0.1 and 0.2 in two cases—with popularity (0.199), and with handwriting (0.154). The figures in brackets are the values for boys; for girls the values are somewhat smaller. The order of the probable error is  $\pm 0.015$  in each case. Professor Pearson considers that his data "seem to shatter three widely if not universally accepted beliefs. Firstly: General Intelligence and a variety of psychical characters seem practically to be unchanged throughout the whole range of school life. It is not therefore possible for the teacher to modify them. It is the parent, not the teacher, who provides the metal; all the teacher can do is to give it an edge and temper it. Secondly: General health changes exceedingly little during the whole school period. Health and Intelligence are correlated, although not very markedly. While recognizing this association of Health and Intelligence, it does not seem feasible with the present state of medical knowledge to improve Intelligence by modifying Health. In the middle classes, where environmental and medical care of

children is the rule, we do not find any appreciable advance in Health during school years. We are forced to recognize that on broad lines Health and Intelligence are innate characters, chiefly determined by inheritance. Thirdly: There appears to be no foundation for the widely spread opinion that Health is a governing factor of temperament."

There will be no difference of opinion as to the value of this exact and lucidly presented analysis of a body of data gathered by experienced observers in many schools. There may be a difference of opinion as to the justice of the remarks quoted. We shall not ourselves take part in this discussion, because Professor Pearson emphasizes the fact that the bulk of his data is drawn from middle-class schools, and, so far as we are aware, it is with respect to elementary schools that opinions resembling what Professor Pearson asserts to be universally accepted beliefs have been at all widely expressed by medical men. We are not, indeed, sure that even in that field it has been asserted without qualification that medical care can modify intelligence. What we think has been universally asserted is that underfed, sickly children suffering from remediable defects—uncorrected errors of refraction, septic mouths, dirty scalps—are not in a state permitting them to profit by the educational advantages proposed in our system of elementary education. This belief, whether true or false, is not shattered by the present analysis.

Professor Pearson writes: "Beneath the ceaseless flow of life the feeble mind of man catches now and again some glimpse of deep biological purpose in the universe; he sees it mid the shifting vortices of the flood only too obscurely. Nature does not work through man but on man; and she works not with his ineffectual tools but with her own all-powerful machinery. She made by variation, by inheritance, and by ruthless extermination the moderately amiable, the moderately intelligent man of to-day out of an untamed and mordacious precursor. Is it not blind audacity for man to claim that by the aid of his puny, if undoubtedly useful, little polishing tools, such as education and medicine, he can achieve as much in a school life as Nature with her omnipotent mechanism has taken in all probability a quarter of a million years to produce? If man would throw himself into sympathy with Nature's purpose, let him appreciate to the full extent the potency of her methods, and endeavour as his slender strength may permit to use her tools." This is finely said, and, in an age of braggarts proclaiming that if only this or that were done disease and sorrow would be banished, the truth it enforces is not very likely to be misused. But metaphors, if good servants, may be bad masters; should anyone conceive "Nature" as a learned lady with the features of Britannia on our pence, study of the Registrar-General's annual returns, and perception of the fact that in 1918, a year of deadly pestilence, the annual rate of mortality which appalled us was within 0.1 per 1,000 of what Farr fifty years before had proposed as a possibly attainable standard, will convince him that the good dame's rate of movement away from Frightfulness has quickened during the past two generations.

When we drop metaphor, we may recollect that all we do and hope is part of "Nature," that confidence in our useful little polishing tools of medicine and education was implanted in us by "Nature," and that these selfsame tools also belong to "Nature's" all-powerful machinery.

<sup>1</sup> *On the Relationship of Health to the Psychical and Physical Characters in School Children.* By Karl Pearson, F.R.S. Drapers' Company Research Memoirs, Studies in National Deterioration, IV. Cambridge: University Press; London: H. K. Lewis and Co., Ltd. 1923. (Med. 4to, pp. 77; 39 diagrams. 15s.)

at all stages of the disease, in its initiation, in its development and in its progress, then and only then is the natural history of heart disease understood."

In the second place, the student must become really keen on the search for the etiology, the primary and second causes, of the morbid condition he is investigating. One frequently hears it said that the clinical student learns best by seeing a great number of cases, and that London with its immense population therefore affords the best opportunity for clinical study. I am afraid I do not agree. Of course, the wider the experience the better; but it is not the superficial survey of many cases but the understanding of a few which really educates the student. Comprehension and not repetition is the strength of memory; and it is obtained as the mind really explores and observes, and discovers for itself the causation of the condition. Nowadays we look for guidance (a) to bacteriology and pathology, (b) to clinical character and symptomatology, (c) to laboratory confirmation, and (d) to social factors. There is much new knowledge available, but 150 years ago at Edinburgh, William Cullen was proclaiming all the enduring principles, and his plan of studying each case has not been greatly improved upon by some modern prophets. Nevertheless, of course, he taught before the industrial revolution. The people had not swarmed into the towns (where four-fifths of them now live), the factory system was not dominant, industrial fatigue—a fertile source of physical and psychical impairment—was not appreciated, and the general stress and strain of modern life was less than now. Mr. G. M. Trevelyan tells us that the second half of the nineteenth century is "the story of the building up of the new world, of a wholly new type of society, infinitely more complicated and interdependent in its parts, more full of potentialities for progress or disaster, than anything the world has before seen," and this must be taken into account. Moreover, the growth of knowledge was awaiting Darwin, Pasteur, and the growth of knowledge was awaiting Darwin, Pasteur,

THE TEACHING OF OBSTETRICS AND GYNAECOLOGY.

BY

JOHN S. FAIRBAIRN, M.A., M.B., F.R.C.P., F.R.C.S.

SINISTRE PHYSICIAN, ST. THOMAS'S HOSPITAL.

Lastly, the student should habituate himself to think widely and responsibly of the means of prevention in their whole range. Poverty, industry, personal habits, social conditions, channels of infection, must be considered as well as the grand category of the therapeutics which prevent—drugs, vaccines, serum, organic substances, sunlight, electricity, radium, massage, psychology—and the still wider factors of environment. He is to learn by ingenuity to apply and adapt all knowledge to the harnessing of disease as a whole. The patient is to be cured, yes, but out of the patient is to be wrought an understanding of, and an attack upon, and the prevention of, the particular disease from which he suffers. It may well be that the student cannot practise prevention as he learns to practise the cure, for the issues raised are beyond his immediate control. But when he enters upon his life's work as a medical practitioner he will find that it is required of him that he shall take an essential part in the vast national and international machinery now in being for the conquest of disease. There are not less than a score of Acts of Parliament which impose public preventive duties upon him as a medical practitioner. He must know how to comport himself in relation to those laws. But more than that, his private patient is concerned not only with the alleviation of his malady, he is anxious about the future and his capacity to work, and he asks, "What can I do to prevent this?" Surely, that is a very cogent and penetrating question for the medical practitioner to answer. His answer, and its wide promulgation and proper interpretation, is the fulfilment of his splendid part as the missionary of Preventive Medicine. For his comfort he may remember that to prolong human life and make it fuller, better, and more effective, is the "master task of mankind."

no final foundation on which practice must be built, and no opportunity must be lost of interesting the student in all phases of the normal functioning of the reproductive system. In the ante-natal clinic he will be taught the object of detecting and remedying any deviation from the normal. For the first time in his training the student sees patients, of whom the vast majority are not ill, in order to pick out occasional cases in which trouble may be brewing or may be feared in the future. He will learn the examination of women in all stages of pregnancy, and the warning signs that enable its disorders to be detected early and prevented in labour force. In the wards the investigation and treatment of the more serious diseases of pregnancy will be carried out with the help of biochemical and other laboratory methods, and the conduct of labour and the nursing mother and her infant will likewise be followed with the same object of keeping healthy patients in health, and observing the physiological processes of involution, lactation, and the early development of the child. The following in the infant clinic is the natural corollary of this part of the work.

The diseases of the reproductive tract are largely represented by (1) infections, due to gonorrhoea and puerperal sepsis, (2) mechanical lesions resulting almost entirely from injury at childbirth, and (3) new growths. Of these the first two are preventable and should be presented first to the student, and the third last.

Training in midwifery cannot be expressed merely in terms of attendance on labour, with and without the hospital, but must include all the machinery of what is commonly termed a maternity centre. Pregnancy, labour, lying-in, and lactation are physiological states and in all of them our primary object is the maintenance of the physiological and the avoidance of the pathological. The physiological study of reproduction is, therefore, the essential part of the pathology.

A beginning may be made by outlining the changed view of what is included under Midwifery and the Diseases of Women. Though the title is double, the subject is not: it is the study of normal and abnormal reproduction and the diseases of the reproductive tract in women, and it cannot be taught in two separate pigeon-holes as obstetrics and gynaecology. It must be presented to the student from the aspect of preventive and curative medicine—midwifery representing chiefly the preventive and gynaecology the curative and reparative side—and the more the subject can be widened to include over the whole reproductive cycle—from one generation to the maturity of the next—the more educative will it be.

Nothing in midwifery can be expressed merely in terms of attendance on labour, with and without the hospital, but must include all the machinery of what is commonly termed a maternity centre. Pregnancy, labour, lying-in, and lactation are physiological states and in all of them our primary object is the maintenance of the physiological and the avoidance of the pathological. The physiological study of reproduction is, therefore, the essential part of the pathology.

NEW AND WIDER VIEWS.

The shortcomings of the old midwifery training must have passed an examination in anatomy and physiology, satisfied forth into the out-door maternity district to pick up, under no supervision whatsoever, what they could of the practice of midwifery under the worst possible conditions. Lamenting past deficiencies will, however, serve no useful purpose and time and space will be better occupied in describing present methods and ideals, so far as can be done by one teacher, speaking on behalf of many.

NEW AND WIDER VIEWS.

A beginning may be made by outlining the changed view of what is included under Midwifery and the Diseases of Women. Though the title is double, the subject is not: it is the study of normal and abnormal reproduction and the diseases of the reproductive tract in women, and it cannot be taught in two separate pigeon-holes as obstetrics and gynaecology. It must be presented to the student from the aspect of preventive and curative medicine—midwifery representing chiefly the preventive and gynaecology the curative and reparative side—and the more the subject can be widened to include over the whole reproductive cycle—from one generation to the maturity of the next—the more educative will it be.

Nothing in midwifery can be expressed merely in terms of attendance on labour, with and without the hospital, but must include all the machinery of what is commonly termed a maternity centre. Pregnancy, labour, lying-in, and lactation are physiological states and in all of them our primary object is the maintenance of the physiological and the avoidance of the pathological. The physiological study of reproduction is, therefore, the essential part of the pathology.

tion; and recently in shipments of apples from Australia thus affected the condition was traced to an excess of carbon monoxide accompanied by a low oxygen concentration in the holds. In an illuminating prefatory note to the special report Mr. W. B. Hardy, F.R.S., the director of the Food Investigation Board, draws attention to the physiological or functional as distinct from the infective nature of this abnormal condition. In other words, it is not a condition that is due to moulds or infective organisms. The apple, as a living organism, breathes, and "brown heart" is the result of physiological suffocation. The researches of Kidd and West entailed a study of its respiration and analysis of its internal atmosphere—that is to say, of the air enclosed in certain microscopic canals which traverse the flesh of the fruit. The disease was thus found to be caused by the death and subsequent browning of the internal fleshy tissue when the amount of carbon dioxide in this internal atmosphere was excessive. The external tissue remains undamaged and the fruit appears generally sound until it is cut open, when the fleshy tissue around the heart of the apple is seen to be brown-coloured and rotten. The condition may be caused by a brief exposure to excessive carbon monoxide concentration, and this rather than a prolonged average concentration is the most important factor, although temperature also influences the results. The practical effect of the investigations is that, while the ripening of the fruit can be retarded by a certain concentration of carbon monoxide, and a subnormal oxygen concentration above a certain minimum, without injury, a degree of ventilation is necessary to prevent the carbon monoxide becoming excessive and so suffocating the respiration. These researches also throw light on what is known as "bitter pit" in orchards, a condition in which small, isolated patches of dead tissue appear immediately below the skin of the fruit, causing the skin to sink in after the patches dry out. The whole series of experiments and conclusions are of great interest and of many-sided scientific and economic value. They are an excellent example of the useful work that has been, and is still being, carried out by the Food Investigation Board, which was instituted during the war. It is understood that further researches will be carried out to determine the immediate possibility of an improvement in the method of storage during overseas transit not only of apples but also of other fruits. A report, which will have a definite bearing on this, is being prepared, embodying the results of gas-storage tests with various fruits. The special research was carried out under the direction of Dr. F. F. Blackham, F.R.S.

#### THE INTRODUCTION OF HYPODERMIC MEDICATION.

In the account of Charles Gabriel Pravaz, under the heading "Nova et Vetera" in the *JOURNAL* of August 18th, our contributor made a passing reference to Alexander Wood (1817-84), at one time President of the Royal College of Physicians of Edinburgh (1858-61). Wood was the first representative of the College (1858-73) on the General Medical Council, on which he did yeoman's service for his fellow countrymen by successfully advocating the abolition of territorial and limited licences to practices, thus removing the difficulties previously besetting those migrating from the North to the South of England. His name should also be gratefully remembered as the originator of hypodermic medication; in 1853, taking as his model the sting of a bee, he constructed a small glass syringe with a fine perforated needle point attached, and thus injected morphine hypodermically. Two years later (1855) he published *A New Method of Treating Neuralgia by Subcutaneous Injection*. Curious as it may now seem, the injection was at first, and apparently as a

matter of course, made by Wood's direction into the painful area. Hypodermic injection at a distance from the pain was first carried out by Mr. Charles Hunter, a house-surgeon at St. George's Hospital, in 1858, who as late as 1866 felt it necessary to argue, through twelve pages in the first volume of *St. George's Hospital Reports*, that hypodermic injections of morphine at a distance from the painful spot were really effective—or, in his own words, which then probably appeared bold and now seem unduly cautious, "Notwithstanding the strong current of opinion still in favour of localization . . . distant injections have, with some experimenters, as a rule, been always equally effectual with local injections." Very shortly after this Sir Clifford Allbutt recorded in the *Practitioner* (1869) the remarkably good effects of hypodermic injections of morphine in patients suffering from severe heart disease; this at the time was also rather a bold, though most valuable, departure from paths of strict orthodoxy. Truly "our little systems have their day . . . and cease to be."

#### THE BRITISH ASSOCIATION, LIVERPOOL, 1923.

As already announced, the ninety-first annual meeting of the British Association for the Advancement of Science will be held at Liverpool from September 12th to September 19th. On the opening day there will be meetings of the Council and the Organizing Sectional Committees; at 5 p.m. the General Committee will meet, and at the inaugural general meeting at 8.30 p.m. Sir Ernest Rutherford will deliver his presidential address, on the electrical structure of matter. On Thursday, September 13th, Professor G. H. Nuttall, F.R.S., as President of the Section of Physiology, will give an address on symbiosis in animals and plants. On September 14th, at a joint meeting of the Sections of Chemistry and Physiology, a discussion will take place on the physical chemistry of membranes in relation to physiological science; at 8.30 p.m. on the same day Professor G. Elliot Smith, F.R.S., will deliver a lecture on the study of man before a general meeting of the Association. Saturday, September 15th, will be devoted to excursions. A discussion on the delinquent child will be held on Monday, September 17th, at the joint meeting of the Sections of Psychology and Education. Professor J. J. R. Macleod will open on the same day a discussion in the Section of Physiology on insulin and its value in medicine, and Dr. Edridge-Green will read a paper in the same section on the effect of the blood in the retina on colour equations. A scientific soirée will be held on the evening of September 16th, when exhibits will be shown illustrating the results of recent work in various departments of science. Throughout the course of the week an exhibition of scientific apparatus will be on view in the Central Technical School, and the Air Ministry is arranging a meteorological demonstration. Most of the thirteen sections will hold their sessions in the buildings of the University of Liverpool. The reception room and administrative offices will be held in St. George's Hall. In connexion with the meeting a series of public lectures to citizens and children will be given by members of the Association.

#### HETEROMORPHOSIS.

It is not uncommonly thought that morbid histology is practically worked out, and no doubt it has been thrown into the shade by the attractions of other branches of pathology, and especially, perhaps, by the study of metabolism, biochemistry, and disorders of function. But that morbid histology affords plenty of scope to research workers is shown by Dr. G. W. Nicholson's papers in the

have been done to secure a physiological labour for this woman?

#### THE Gynaecological Side.

Early in the third month clerking in the gynaecological department will be begun, spare time being portioned out between the maternity and infant clinics. Diagnosis is learnt most easily on patients in the wards and bimanual examination on those under anaesthesia, but, as the outpatient approach more closely to conditions met with in general practice, close attendance on them is especially important. Provided attention is not unduly concentrated on dramatic and striking operations and the most made of minor procedures, the teaching of gynaecology is simple and straightforward compared with that of midwifery; and that the opportunities for pelvic examination of women are more limited, it differs but little from clinical teaching in medicine and surgery. The nervous and psychological element is intimately bound up with sexual and reproductive disorder and this aspect is easily overlooked, but ought to be kept before the student, for its importance in practice can scarcely be overestimated. The student, having already learnt his general pathology, only requires such features as are peculiar to the reproductive function to be emphasized, and they can be best illustrated by demonstrations of material from the department, the naked-eye and microscopical investigation of which is part of the case record.

#### CLINIC IN DIVERSITY.

All schools and teachers have their own individuality, determined more by variations in the atmosphere in which teaching is conducted than in method. Thus the writer's own atmosphere may have distorted the perspective of this sketch by making some features stand out too prominently and others recede too far into the background; but the general impression may be taken to represent the present-day aspirations and ideals of those who, in this subject, endeavour to train up the student in the way he should go.

## The Profession of Medicine.

where the number of abnormal cases in proportion to the number of students is sufficient to provide the necessary material. Difficult and operative cases must be seen by all students in residence and within call. The diagnosis of obstetric complications is acquired in the ante-natal clinic as well as in the labour room, obstetric manipulations are taught on the dummy and focus and by making the utmost of the hospital material by demonstration to as many students as possible. Many of the lesser procedures—low forceps and the like—will afford opportunities for the student in the later stages of his training to carry out these operations under the supervision of his teachers. Preventive measures during pregnancy have so greatly diminished the proportion of complicated cases—especially mistakes between the head and pelves, malpresentations, and obstructive complications—that the number of obstetric difficulties available for teaching are correspondingly less. The high forceps operation, craniotomy, and version for shoulder presentation are now rare events, and delivery by the breech is reduced, by turning some weeks before term, to a small percentage of its former frequency. There is less alteration in the treatment of the albuminuria of pregnancy and *ante-partum* haemorrhage, in which the management largely consists of rest in bed and observation to determine whether interference is called for and, if so, the most appropriate moment and method. Errors of observation, emergencies cases sent into hospital, and unavoidable complications will always provide a certain number of difficult labours, which must be discussed with the students in the same attitude of prevention that pervades all their teaching. The first question will be: Could this complication have been foreseen, and, if so, how did it come to be overlooked? Had it been foreseen, what better could have been done and what troubles to mother and child might have been avoided? This attitude of mind should be maintained even towards such trifling procedures as the low forceps operation by considering the factors that interfere with uterine efficiency. Were any of these present in this case and could anything

#### INTRODUCTION.

For long past the annual Educational Number of the British Medical Journal has appeared at this time of year, when the opening of a new session is at hand. The remarks that follow, on the profession of medicine, are addressed more particularly to intending students and their parents. It would be out of place to discuss medical politics at large, but the occasion may be taken to touch briefly on a few current matters affecting professional study and practice. If an opinion is expressed on debatable topics it must be understood that our object is not to lay down the law, but to put certain considerations before those who think of devoting their lives to medicine, and thus help them to judge of their fitness for the calling and of the prospects it holds out. There is no profession for which a special vocation is more necessary. And (it should perhaps be added) there are few professions in which a fortune is less likely to be made.

Our present issue, then, is largely a guide to the steps that must be taken in order to become a legally qualified practitioner. It contains also certain sections intended for younger members of the profession who may be in doubt as to the path in medicine they should choose as a career, and a section on the facilities for post-graduate study in Great Britain. The particulars given under these two main heads are founded for the most part on official information, and are arranged along the customary lines; but, following last year's plan, we publish in this issue two introductory articles on particular features of medical education, each from the pen of a recognized authority. Sir George Newman writes on the need for permeating the

students' whole course of training with the spirit and methods of preventive medicine, and indicates the steps already taken to attain that end by reformation of the curriculum. Dr. John Fairman, in his note on the teaching of obstetrics and gynaecology, discusses certain ways in which the "preventive idea" may be carried further into this most important branch of medical education. The two articles are thus complementary, each emphasizing, one in general terms and the other from a special point of view, the significance of prevention in the study and practice of medicine. Apart from these and other special articles, the prospective student will find in subsequent pages an account of the course of education required of him, the places where this training can be obtained, and the universities and other bodies which test the knowledge gained and issue degrees or diplomas entitling successful candidates to become registered medical practitioners.

#### PORTALS OF THE PROFESSION.

As will be seen from a perusal of the articles in this issue, there are many portals through which admission may be obtained to the *Medical Register*, which is the official statutory list of qualified medical practitioners. Yet the medical courses of all the universities and corporations in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same in all. Within these broad lines, however, there are many differences between the requirements of the various teaching and examining bodies. The choice should therefore be made early, so that a definite plan may be followed throughout the years of study. To prevent a false step at the outset

Hospital. There will also be a special course of instruction in infants' diseases at the Infants' Hospital, from September 3rd to 21st, a course in ophthalmology at the Central London Ophthalmic Hospital, from September 3rd to 29th, and a course in dermatology at St. John's Hospital for Diseases of the Skin, from September 17th to October 13th. Particulars of the courses may be obtained from the Secretary, Fellowship of Medicine, 1, Wimpole Street, W.1.

WE announce in our Service notes this week the promotion of Surgeon Captain Arthur Reginald Bankart, C.V.O., R.N., now serving in H.M. Yacht *Victoria* and *Albert*, to Knight Commandership of the Royal Victorian Order. It was largely owing to Sir Reginald Bankart's personal influence that members of the British Medical Association attending the Annual Meeting at Portsmouth last month were able to visit the Royal Yacht.

## VARIETIES OF SMALL-POX.

BY

JOHN C. McVAIL, M.D., LL.D., F.R.F.P.S.

The extensive prevalence of mild small-pox in England last year and this year has naturally created much medical interest in the subject, and the purpose of this article is to review briefly the general position.

The subject is far from new. As pointed out by me in the Milroy lectures in 1919, Sydenham referred to small-pox without eruption. Wagstaffe, in the eighteenth century, said of small-pox that "there is one sort in which a nurse cannot kill, and another which even a physician can never cure." Jenner, in 1789, seven years before his first vaccination, discussed the question whether a mild type of small-pox then existing might not be used for protective inoculation in preference to matter from the ordinary disease. Adams, of the London Small-pox Hospital, wrote on "pearl-pox" in 1806. About a century ago Professor Thomson of Edinburgh defended at much length the proposition that small-pox and chicken-pox are one disease, and, if I mistake not, Hebra was of the same opinion. In the eighteenth century names such as stone-pox, horn-pox, water-pox, swine-pox were not uncommon, but probably referred mainly to modified second attacks of small-pox, which occasionally occurred at long intervals after a first attack, particularly, no doubt, if the first attack had been mild.

In recent years mild or modified small-pox has been much heard of in various parts of the world—in Trinidad, the United States, Canada, Australia, and South Africa. Some outbreaks have been the subject of careful and valuable investigation, as recorded in the *Proceedings of the Royal Society of Medicine* and in the *Transactions of the Society of Tropical Medicine and Hygiene*. Various names have been applied to such outbreaks in the countries where they have occurred—alastrim, Cuban itch, or, in South Africa, amaaas, meaning milk-pox. In one instance such a cognomen was adopted to allay alarm in the country surrounding the invaded area, lest the alarm should prevent the bringing in of necessary supplies. But such nomenclature leads to confusion, and whatever is variolous should be so acknowledged, whether mild or severe.

In this country a most puzzling and anomalous outbreak in Suffolk and Norfolk was investigated in 1919 by Dr. Monckton Copeman, whose report, published by the Ministry of Health in its 1919-20 volume, is of much interest. In a total of 31 cases only four were seriously ill, and the only death was that of a puny unvaccinated baby. The infection, it was supposed, might have had its origin in Egypt, and in the course of his early visits Dr. Copeman expressed the opinion that "as the disease gradually became more acclimatized" it would tend to "approach

more nearly to the type of small-pox as ordinarily met with in this country." That, as it turned out, was the course of events; in the later cases the severity of the symptoms was markedly greater, and backache, for example, was added to the initial headache.

In that connexion a very important question is whether the exceedingly mild variola at present prevalent in Gloucester and elsewhere will continue to breed true—will be mild throughout the whole of its prevalence, or will, whether by degrees or suddenly, change its character and take on the classical appearances of small-pox so well known throughout the world. No certain answer can be given to the question. That close and competent observer, the late Dr. Franklin Parsons, related how "in one town in Lancashire there were outbreaks from two sources concurrently; one could be traced to the cases imported from America, of a mild type, while another was traceable to the infection which had come across from Paris via London, and that was severe." Indeed, the fatality rate from mild small-pox in this country is now even lower than in the prevalence of 1902-5, when the American type first became prominent on these shores. At that time fatality rates ran from about 1 per cent. to 4 or 5 or 6 per cent., including vaccinated and unvaccinated, but no large outbreak that I know of had so low a rate, say, as last half-year's two or three deaths in over 1,200 cases. In America we in this country have generally understood that mildness of type had become established so that the disease was in some places being regarded as endemic, and not worth troubling about. Now, however, the picture has suddenly changed. The United States Treasury Department, in its Public Health Report for the week ending June 22nd, 1923, has a note entitled "Increasing virulence of small-pox in the United States," and accompanies it by an important table of statistics, headed "Small-pox cases and deaths, and deaths per 100 cases, in 275 American and Canadian cities, 1920, 1921, and 1922." The population of the cities is not stated, but there is full information as to the number of cases and of deaths in each year for the total cities, and for ten or eleven "special cities." Canadian cities to the number of 29 are included in the 275, because the data are contained in a statistical bulletin of the Metropolitan Life Insurance Company. Taking the cities as a whole, there were 30,328 cases in 1920, 23,977 in 1921, and 8,709 in 1922. The numbers, therefore, have decreased. But the fatality rate was 0.6 per cent. in 1920, 1.1 in 1921, and 5.5 in 1922. In the special cities jointly, the fatality rate in 1920 was 0.2 per cent., in 1921 8.5 per cent., and in 1922 no less than 28.4 per cent. Of individual cities, Kansas and Denver were very hardly hit, the deaths being at the rates of 45 and 31 per cent. It is surmised that the outbreaks in these two towns may have had the same unknown origin, but whatever the sources it is clear that either the mild type has changed or a severe type has taken its place in these and other cities.

In no country can there be any certainty as to the future of small-pox, and the only prudent course is to be prepared against whatever may come. Vaccination, renewed as required, can prevent both severe and mild small-pox. The one form protects against the other, vaccination protects against both, and Chapin, when the mild form was spreading in America, pointed out, further, "that persons who have had the mild type are equally immune to vaccination." As to diagnosis, I would call attention to Dr. Wanklyn's article in the *BRITISH MEDICAL JOURNAL* of July 21st (p. 106), and would also remind the profession that the Ministry of Health has appointed for each part of the country a consultant skilled in all that relates to variola. When doubt arises there should be no delay in calling in this aid.

in this direction. Beyond the qualifications which admit to the *Medical Register*, most of the licensing bodies confer higher titles, such as Doctor of Medicine or Fellow, after further tests. For the career of a consulting physician the M.D. degree of a university is usually necessary, and also the membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which practice is contemplated. In the same way, Surgeons should be sought by those proposing to devote themselves to surgery. There are also diplomas in a growing number of special branches of work, such as public health, tropical medicine, ophthalmology, radiology, and mental disease, which are superfluous for most practitioners, but either useful or indispensable for the medical man or woman who wishes to specialize in these subjects.

FINANCIAL AND SOCIAL CONSIDERATIONS.

The financial aspect of medicine cannot be discussed here at length. Three remarks must suffice: Medicine is not to be regarded as a path to fortune, and anyone who enters our profession with the sole idea of making money has mistaken his calling. The competent practitioner, at any rate in urban districts, can always make a living, but the main reward of the medical life is the knowledge of good work well done. Whatever the branch of practice chosen, there are few doctors who become what a business man would consider even moderately rich by the exercise of this profession.

But if medical practice, from the financial point of view, offers little more than a means of livelihood, in its social and intellectual aspects the prospect is bright. The culture which once belonged to the physician alone, entitling him to his place among members of the learned professions, has spread into all ranks of the practitioners of medicine. The great improvement in the education, general as well as technical, of the practitioner, has added much to his influence in public life, and has been a large factor in raising his social status during the past sixty years. No medical specialty is so narrow that it affords scope for intellectual achievement in an atmosphere of service for others.

THE NUMBERS OF MEDICAL STUDENTS.

Nearly five years have passed since the war ended, but one effect was a great increase in the number of medical students, both men and women, but especially women. This matter has often been discussed in these pages, so we give here an outline only of the story. It may be read in conjunction with the note at page 355 on the numbers of the profession. In the thirteen years before the war the annual entry of medical students in Great Britain and Ireland averaged 1,400. During the war period the total number of students pursuing their studies in the various medical schools was ascertained and made public from time to time. These figures showed that from 1914 to 1919, although many left to serve with the Forces, the whole number actually studying in the schools was growing steadily larger. Thus, in May, 1916, the total was 6,103; in May, 1918, it was 7,630; and in the following January it had risen to 9,480. After the armistice the total figures were no longer published, but the number of entrants recorded in each year told its own tale. Thus, during 1919, when demobilization was in active progress, 3,420 new students were registered. The number of new students in 1920 fell to 2,531, and in 1921 to 1,808. In 1922 the national standard demanded by some of the licensing bodies. The great increase after the armistice threw a heavy strain on the schools, and the subsequent fall in the entries was welcomed, both by the overcrowded teaching

institutions and by those who feared there might not be work enough to go round when the students of to-day become qualified. As it is, the ratio of medical practitioners to population is greater now than at any time in the past half-century. The new regulations which came into force at the beginning of this year should do something to keep the number of students within manageable bounds.

PRIVATE PRACTICE: THE OUTLOOK.

The prospects held out by the various public medical services are indicated in later sections. Here we may note very briefly some circumstances that have a bearing on private practice. In the first place, efforts are being made to bring professional training more into line with the growth and differentiation of medical science, and so to raise the level of medical practice; it was with this in view that the students' curriculum has lately been recast. Next, the fundamental importance of the work done by the general practitioner is better understood, and it is more fully recognized that an efficient medical service for the community must be based upon the individual skill and closer touch with the aims and methods of preventive medicine.

The National Insurance system, now more than ten years old, has already had a profound influence upon general practice. The Insurance Medical Service comprises nearly 14,000 practitioners, some doing much work among insured persons, others little. If the freedom of family practice has been restricted by the Insurance Acts and Regulations, they have probably rendered it easier for a doctor to make an assured income out of attendance on working-class patients. The full effect of the insurance system upon the medical profession cannot as yet be gauged. Some of its most objectionable features have been removed through the efforts of the Insurance Acts Committee of the British Medical Association, which is the central executive of the Local Medical and Panel Committees of the country, and all negotiations with the Government. But the capitation rate of payment for the medical attendance and treatment of insured persons is once again under revision, and the future of panel practice turns to a large extent upon the value set by the State upon the general practitioner and his work.

Increasing contact with public duties and official requirements not only makes new demands on the practitioner, it adds uncertainty to his outlook. Thus a recent writer on medical practice predicts that in another two generations doctors will be servants of the State, meaning by this that a class of State practitioners will be formed who will devote their whole time to insured persons and their dependants. Mr. Sidney Webb, speaking from the chair at the last annual Conference of the Labour Party, indicated 1926 as the date of Labour's accession to power, but affirmed that our next masters will not try to do everything at once; each step towards their goal will (he said) depend on gaining the assent and support of the majority of the people. This, for what it is worth, suggests that the setting up of a whole-time salaried State medical service, towards which the Labour Party is understood to lean, may perhaps be deferred until such time as it is definitely favoured by the greater part of the electorate, but it is all rather disturbing, and the future of private practice is difficult to forecast.

PROFESSIONAL UNCAVATION.

Obviously, in these times of social and professional change the doctor needs a strong sense of *esprit de corps*; the effects of modern measures are apt to be so far-reaching that no practitioner, whatever his work or position, can safely stand aside from this fellows. It follows, therefore,

hall of the General Hospital by Lieut.-Colonel F. E. Seely, President of the hospital, and other officials, and inspected one of the surgical wards, which during the war was used for the treatment of military patients, exchanging a few words with the patients who were being treated there. He then proceeded from the hospital to the Nurses' Home, upon which is an inscription commemorating the great war, and opened the door with a golden key. The new home was designed by Mr. Robert Evans, in collaboration with Dr. D. J. Mackintosh of Glasgow Royal Infirmary.

## Scotland.

### CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Board, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just concluded with the following results: Out of 135 candidates who appeared for the examination 120 passed. Of the successful candidates 29 were trained at the Royal Maternity Hospital, Edinburgh; 42 at the Royal Maternity Hospital, Glasgow; 4 at the Maternity Hospital, Aberdeen; 7 at the Maternity Hospital, Dundee; 6 at the Queen Victoria Jubilee Institute, Edinburgh; 12 at the Cottage Nurses' Training Home, Govan, Glasgow; and the remainder at various recognized institutions.

### LOANS IN AID OF EDINBURGH BUILDING.

Edinburgh Corporation has had under consideration a number of applications from persons who desire to take advantage of the recent powers conferred on local authorities to grant loans in aid of building houses. This is the first list of applications, comprising 72 houses. One-half are applications by employers erecting houses on behalf of miners; one-third are for houses of the better-class kind for the occupation of working-class proprietors; and the remainder are for individual houses intended for occupation by the applicants. With regard to the amount that would be advanced, the Housing Director suggests that on a building estimated at £550 with a probable rental of £32, the amount of advance with subsidy might be from £460 to £500.

### SCOTTISH MENTAL HOSPITALS' ACCOMMODATION.

In a report to the Aberdeen District Board of Control, Dr. H. C. Marr, Commissioner of the General Board of Control, expresses the hope that it will not be found necessary to extend the accommodation of Kingseat Mental Hospital, as the present institution is large enough to obtain a maximum of efficiency and there are at present many vacant beds in other institutions throughout Scotland. Also relief may be expected in the near future by extended amplification of the Mental Deficiency and Lunacy (Scotland) Act of 1913, which owing to the war and subsequent financial restrictions had its operations greatly limited. It is expected that mental defectives will be dealt with under the Act elsewhere than in a mental hospital. The hospital, with its elaborate medical equipment and facilities, and its essentially curative aims, is unsuited for the custodial care and occupational education which are necessary for mental defectives.

### FAITH HEALING IN SCOTLAND.

An important sign of the times in regard to the spread of the practice of faith healing by mass suggestion was witnessed in a religious festival held on August 15th at the grotto of Our Lady of Lourdes in Carfin, to celebrate the feast of the Assumption. Large crowds flocked to Carfin from all parts of the West of Scotland, the number of persons present being estimated at close on 50,000. In the forenoon a visit was paid to the grotto by 300 Italian pilgrims drawn from all parts of Scotland. Headed by a banner with the device, "Ave Maria," the procession of men, women, and children marched through the village singing hymns. On arrival at the grotto, flowers were presented by children among the processionists to the priest in attendance, who placed them on the shrine. In the afternoon there was a similar procession of cripples composed of inmates of Roman Catholic institutions in Edinburgh and the East of Scotland. On their arrival at the grotto,

special prayer and invocation was offered for the sick and afflicted, and the vast crowd repeated the words of the prayer, "Lord, say but the word, and I shall be whole." Whether any physical benefit accrued to any of the cripples is not known.

## Ireland.

### COUNTY GALWAY BOARD OF HEALTH.

The County Galway Board of Health has published its first annual report. In a foreword Mr. W. T. Cosgrave—who, when Minister of Local Government, was mainly responsible for the amalgamation of unions in Ireland—states that he has great hopes that in the County Galway and throughout the Free State the new schemes established for the relief of the poor and the treatment of the sick will be administered prudently and humanely. The report states that the medical and surgical staff of the County Hospital consists of a visiting physician, a house-physician, and a house-surgeon; and an honorary staff appointed by University College, Galway, consisting of two surgeons, a gynaecologist, obstetrician, ophthalmologist, and otologist. In February, 1922, the Galway Health Board suggested the grading of dispensary districts with graded salaries and a promotion system. The Local Government Department pointed out that it would be inadvisable to proceed with this scheme until the whole scheme of Irish Medical Services is remodelled. To meet, however, the grievances of the dispensary doctors the Health Board agreed, as a temporary measure, to pay each of its dispensary doctors a minimal salary of £300 per annum. The Local Government Department refused to sanction the proposal except in the case of doctors with ten years' completed service. Newly appointed doctors must commence on an initial salary of £250 per annum with annual increments of £5 until a maximum of £300 per annum is reached. The report states also that during the year under review there were performed 2,771 vaccinations, and that there were treated in the dispensaries and in the people's homes 9,807 cases. There were 1,927 cases admitted to the different hospitals in the county; of these 121 were fever cases.

### LABOUR AND MEDICAL BENEFITS.

At a meeting of the Irish Labour and Trade Union Congress held recently, a resolution was unanimously adopted demanding that medical benefits be included in the present State scheme of National Health Insurance, and urging on the National Executive to convene a conference of Trade Union Approved Societies to assist in the preparation of a suitable scheme to give effect to this resolution.

## Correspondence.

### MEDICAL CHARITIES.

SIR,—I am sorry my absence from London has prevented me from answering at once the courteous letter of Sir Charters Symonds in which he refers to the statements I made at Portsmouth about the Royal Medical Benevolent Fund. It was because I am a member of the Committee of Management that I was able to speak as I did, and other members know that I simply repeated what I have said in our committee meetings—that new ideas were required in the organization.

I have the greatest admiration for the time given, trouble taken, and work accomplished by Dr. Newton Pitt, but I am sure he could be relieved of a considerable amount of detail work in his secretarial duties if we had a wider business method of administration.

Frankly, after reading Sir Charters Symonds's letter I fail to see any great advancement of the fund in the last twenty years. The figures he quotes for comparison, from 1902 to 1922, are not encouraging. In 1902 income and subscriptions came to £3,946, in 1922 £8,080—the figures have doubled. But alas, the economic conditions have changed, and eight thousand pounds now is nothing like double the value of four thousand pounds of twenty years ago.

I knew that during the last two years special appeals

of life, in the raising of the present standards of physical health and national welfare.

*New Rules for the D.P.H.*

It is important to note the bearing that this develop-

ment of the teaching of disease prevention to all students of medicine has upon the stringent rules which will come into force at the beginning of 1924 for the obtaining of diplomas in public health (see page 391). Fears have been expressed that the stiffening of the requirements will discourage those who intend to go into ordinary medical practice from taking the additional qualification which would specially fit them for co-operation with the health officer of their district. The reply is twofold: Henceforward all new practitioners will have received tuition qualifying them generally for such co-operation, and in addition they are already being systematically educated in "the duties which devolve upon practitioners in their relationship to the State." The balance, therefore, seems clearly on the right side as to the ordinary practitioner, and there will unquestionably be advantages in strengthening the public health service. In America, it may be mentioned, the standard of study for a "doctorate" in public health will at most medical schools probably correspond with that for the new health diploma in this country.

THE MEMBERS OF THE MEDICAL PROFESSION.

A REVIEW OF FORTY-FIVE YEARS.

Since the year 1876 the General Medical Council has kept an analytical record of the number of persons whose names were entered in, added to, or removed from the *Medical Register* in each twelve months. The *Medical Register* has been published annually since the Council was constituted under the first Medical Act of 1858; but up to 1876 no such data as these were ascertained or preserved.

In order to gain a general view of the numerical strength of the medical profession during the past forty-five years we have extracted from the tables and set down in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the total number added annually by registration between 1876 and 1922.

Numerical Size of the "Medical Register."

The figures for each year since 1889 are given in a statistical table published in the current *Register*; the corresponding figures for the earlier years have been taken from copies published previous to 1889.

| Year. | Names added Total No. | in Year. | on Dec. 31. | Year. | Names added Total No. | on Dec. 31. |
|-------|-----------------------|----------|-------------|-------|-----------------------|-------------|
| 1876  | 1,009                 | 22,713   | 1900        | 1,345 | 36,355                | 1922        |
| 1877  | 910                   | 22,600   | 1901        | 1,318 | 36,912                | 1923        |
| 1878  | 996                   | 22,696   | 1902        | 1,275 | 37,232                | 1924        |
| 1879  | 996                   | 22,936   | 1903        | 1,233 | 37,873                | 1925        |
| 1880  | 1,123                 | 22,936   | 1904        | 1,163 | 38,492                | 1926        |
| 1881  | 1,053                 | 22,936   | 1905        | 1,240 | 39,060                | 1927        |
| 1882  | 1,171                 | 22,801   | 1906        | 1,197 | 39,529                | 1928        |
| 1883  | 1,204                 | 23,571   | 1907        | 1,221 | 39,827                | 1929        |
| 1884  | 1,308                 | 23,321   | 1908        | 1,137 | 40,257                | 1930        |
| 1885  | 1,571                 | 23,993   | 1909        | 1,143 | 40,818                | 1931        |
| 1886  | 1,431                 | 25,432   | 1910        | 1,062 | 40,485                | 1932        |
| 1887  | 1,551                 | 27,959   | 1911        | 1,042 | 40,915                | 1933        |
| 1888  | 1,184                 | 27,436   | 1912        | 1,157 | 41,439                | 1934        |
| 1889  | 1,505                 | 28,343   | 1913        | 1,168 | 41,940                | 1935        |
| 1890  | 1,266                 | 29,163   | 1914        | 1,453 | 42,378                | 1936        |
| 1891  | 1,345                 | 29,550   | 1915        | 1,526 | 43,225                | 1937        |
| 1892  | 1,515                 | 30,530   | 1916        | 1,202 | 43,481                | 1938        |
| 1893  | 1,745                 | 30,959   | 1917        | 1,134 | 43,819                | 1939        |

Proportion of Practitioners to Population.

THE GENERAL MEDICAL COUNCIL.

These parallel columns of figures reveal a general tendency during the past forty-five years towards an increase in the ratio of doctors to population. The number of registered practitioners at the end of 1921 was almost exactly double the number at the end of 1876, but the population within that period only increased by about 50 per cent. During the year 1922 the new medical registrations numbered no fewer than 1,824, and there was a net increase of more than a thousand names. If the rate of increase is maintained in the present year, the time may not be far distant when there is one name in the *Medical Register* to every thousand of population.

The General Medical Council was set up by the first Medical Act of 1858, and consists of thirty-eight members, six of whom are elected by the medical profession, and are nominated by the Privy Council, and the remainder are representatives of the universities and such medical corporations of the United Kingdom as have a statutory right to issue diplomas. Under the Dentists Act, 1921, three additional members have been appointed by the Privy Council for dental business; the Council's headquarters are at 44, Hallam Street, Portland Place, W.1, and it has branch offices at 20, Queen Street, Edinburgh, and 35, Dawson Street, Dublin. Its duties are to control the medical and dental professions in the interests of the general public, and to that end to maintain a register of legally qualified medical practitioners. It is admission to the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person a legally qualified practitioner. The Council is bound to admit to the *Medical Register* those who hold the qualifications granted by the bodies represented among its members, but it exercises supervision through the Privy Council over the terms on which those bodies grant such diplomas or degrees, and it can erase from the *Medical Register* or the *Dentists Register* the name of any medical practitioner who has been convicted before a court of law of an ordinary crime or of a serious offence against public order, or who is proved before the Council itself to have been guilty of certain actions which the Council regards as professionally "infamous." Its disciplinary powers are limited to legally qualified practitioners, and it has no control whatever over irregular practitioners of any kind. In that respect it differs from the Midwives Board in England and Scotland, which can penalise unqualified midwives, even if they make no pretence to be on the midwives roll, and from the Dental Board of the United Kingdom, which, now that the Dentists Act, 1921, is in operation, can prosecute unregistered persons practising dentistry. An account of the recommendations that the Council has drawn up in respect of the education of medical students here follows.

Registration of Medical Students.

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given below. As from January 1st, 1923, candidates must produce evidence (a) that they have attained the age of 17 years; (b) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom; (c) and in addition thereto that they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies. Application for the division of the United Kingdom in which Registrar for the registration should be addressed to the

arguments to disprove the opinion that "all forms of mesoblastic tissue are interconvertible," or that every fibroblast in the body, if subjected to a suitable environment, will and indeed must assume the functions and therefore the structure of an osteoblast. Nor does he help us to an understanding of how the first osteoblast arose in the animal series. His paper has done nothing to upset my belief in an epigenetic mechanism of growth.

It does not matter in the least whether Sir William MacEwen or I be right or wrong in our interpretation of development and growth. All that really matters is a better knowledge of the truth. This is, in my opinion, the real importance of the doctrine inculcated by him. Its true purpose will have been served only if it incites us to further research and thought. Will we, who work in special fields, show our worth by accepting the doctrines laid down by any man or number of men, however great they be, when we are convinced that they are wrong, because every fact known to us in our small corner of knowledge cries out against their acceptance? This is the course you advise us to adopt in your leading article, or so I read it. I vigorously, though humbly, protest against it.—I am, etc.,

Guy's Hospital, S.E., Aug. 18th.

G. W. NICHOLSON.

#### MEDICAL MAGISTRATES.

SIR,—Dr. Tyson has expressed in better language than I can the opinion I have held for some time past, and put forward in vain. But I would go further, and suggest that whenever possible a medical man with experience in lunacy or mental deficiency should be given a seat on a magisterial bench. By such means a considerable number of mental deficiencies would be enabled to receive appropriate treatment, and also relieve magisterial courts of many constantly recurring cases.—I am, etc.,

HUBERT C. BRISTOWE, M.D.Lond.

Wrighton, Somerset, Aug. 20th.

SIR,—I am pleased to notice in the current issue of the JOURNAL a correspondent emphasizes the importance and desirability of having more medical men on the magisterial bench. There are many cases, such as bastardy claims, where the knowledge and experience of a medical man are most useful in helping to sift the evidence and in coming to a just decision.

At quarter sessions many years ago a man charged with a serious crime, who was an epileptic and had had a seizure previous to the commission of the crime, was found guilty and was about to be sentenced, when I was able to point out to the chairman that some of the most atrocious and motiveless crimes are committed in the dull and half-stupid condition following an epileptic fit. The chairman was glad to have the information, and although the question of responsibility had not been referred to in the evidence, the prisoner was discharged.—I am, etc.,

Winstord, Cheshire, Aug. 20th.

G. OKELL.

#### ORAL HYGIENE.

SIR,—I have come to the conclusion that dental caries, pyorrhoea, gastric pollution, appendicitis, and organic decomposition in general is caused by the inane daily scrubbing of teeth with bristles and by the insane use of chemical dentifrices, both of which lacerate and mortify living tissue, destroy epithelial defence, and provide a ready entrance for hostile germs. I earnestly invite attention to the handicap this kind of thing imposes on the natural disinfectants—saliva and mucus.

In ventilating this opinion I do not wish it to be inferred that I disapprove of cleansing the teeth. On the contrary, gentle rubbing with a soft (that is, badger hair) brush and some ordinary soda or other potable mineral water—milk and soda water with a final rinse of the latter to remove taste of milk is also a soothing combination—are procedures which I strongly recommend.

Any brushing of the gums or inside of cheeks I consider an insult to the natural scavengers and any artificial meddling with their job is as insensate as it is destructive.

People from time to time inform me that they use hard brushes in order to clear out foodstuff which becomes impacted between the teeth; to this I invariably object can be effected much more

accurately by the gentle precise employment of a tooth-pick—which, by the way, is (as far as I can gather) employed universally without discrimination of colour—white, black, and yellow. I am informed by many who have travelled much more than I have done that a tooth-pick in some form or other has general application, and that the most beautiful and healthy teeth may be seen in those who never saw (much less used) a tooth-brush. If I am correctly informed on these matters I can only conclude that in our white races our teeth become the victims of what is to them a superfine civilization.

Frequently patients have asked me what they can substitute for soda or mineral water, which is not always available. In such cases, for many years past, I have recommended a saltspoonful of sodium bicarbonate to the tooth tumbler of boiled or filtered water. I do not prohibit the use of well diluted milk of magnesia in those who find it particularly agreeable, and I prescribe its employment in those undergoing mercurial treatment. Under all conditions, I emphasize the words "soft brush and gentle rubbing" with the injunction, "Confine these to your teeth. Do not put anything into your mouth that you would be ashamed to put into your stomach—don't smash up your gums."—I am, etc.,

Buenos Aires.

JOHN O'CONOR, K.B.E., M.D.

#### FREEDOM OF NEGRO RACES FROM CANCER.

SIR,—In your issue of June 30th, 1923 (p. 1116), appears a letter from Dr. F. P. Fouché, in which he states that during his six and a half years of practice in the Orange Free State he had never seen, *inter alia*, a case of appendicitis, or of cancer in any form, in a native. The implication is conveyed, I think, that cancer and appendicitis are, if not unknown, at least exceedingly rare, among the natives of South Africa.

As a matter of fact, although these diseases—so far as one can gather—occur rather infrequently among natives, they are not at all in the nature of pathological curiosities, nor even strikingly infrequent, certainly not unknown. In a series of one hundred consecutive necropsies on native mine labourers conducted by myself in the latter part of 1922 and the first two months of 1923, two cases of carcinoma were observed—one was carcinoma of the pancreas, and glands of the neck in a native male of the Shangaan race, age about 40, the other was a case of carcinoma involving practically the whole of the liver, in a native male of the same race, age about 25.

Dr. Pirie, of the South African Institute for Medical Research, has published several cases of carcinoma in natives.

The vast majority of the natives employed on the mines are between 25 and 40 years of age, and undergo at least two, and frequently three, medical examinations before engagement. Their average stay on the mines is about six months. Under such circumstances one would hardly expect to see many cases of carcinoma even among Europeans, yet we had two cases in only one hundred consecutive deaths in a native population averaging about 80,000.

With regard to appendicitis; at the symposium on "Acute Abdomens" held by the Transvaal Mine Medical Officers' Association in March, 1923, and published in their *Proceedings* for the same month, a number of cases of appendicitis were mentioned. Thus on a mine employing some four to five thousand natives, two cases were operated on in 1921, and three cases in 1923. On one of the mines of our group there were recently three cases within a few weeks.—I am, etc.,

A. J. ORENSTEIN, M.D.,  
Superintendent of Sanitation, Rand  
Mines, Limited.

Johannesburg, July 27th.

#### THE TREATMENT OF TUBERCULOSIS.

SIR,—I should like the opportunity of supporting Dr. Goodwin's views on the treatment of tuberculosis (August 4th, p. 206), though I think the elements of success might be coupled in this order: food and rest; fresh air and sunlight; and another added—that of shelter.

With regard to rest the ideal is rest in fresh air (not fresh air with exertion); in other words, rest of the joint by

now owe to him a debt of gratitude for health restored. The war came, and for him the call was strong. Like many another he gave his untiring best in splendid but exacting home service. At the beginning of the war he took an active part in organizing the Duchess of Westminster's Hospital, and served for a short time with the hospital in France. Later he organized and commanded, under the British Red Cross Society, a special hospital for injuries to the jaw—the first of its kind in the country. Here he worked with indefatigable energy, and for his services he received the C.B.E. at the end of the war. In this work he gave of his best gladly, lovingly, and unsparingly, for above all he loved his fellow man—but he paid the price. Never very robust, he emerged from the war a tired man. He surely needed a long rest, but was soon engulfed once more in the strain of a large practice. The inevitable happened. His friends became anxious. Alas! persuasion to take a long rest came too late, and the end came with tragic suddenness.

**J. EDGAR P. DAVIES, M.B., B.Sc., M.R.C.S., L.R.C.P., Llanelli.**

Dr. EDGAR DAVIES, who was well known in South Wales as an able and hardworking practitioner and a most active member of the British Medical Association, passed away on August 1st in his 54th year. He had retired from practice owing to illness in 1918, and since then had shown a brave and determined spirit in his patient struggle to regain health. He was educated at Llandovery College and the University College of Wales at Aberystwyth. On entering St. Mary's Hospital he was awarded an entrance scholarship in science, and in the early part of his career there passed B.Sc.Lond. and the intermediate M.B. with honours in chemistry and physiology. He held the post of demonstrator in the physiological laboratory, and later, after obtaining the M.B. degree, was appointed house-physician under Dr. Sydney Phillips.

In 1897 Dr. Davies settled in Llanelli, succeeding to a large practice in an industrial area, and became a member of the honorary staff at the Llanelli Hospital. In his work he soon gave proof of the thoroughness of his early training and the richness of his natural gifts. He was an acute and careful clinical observer, shrewd in his deductions, and self-confident and not easily shaken once he had come to a decision. He was a very capable operating surgeon. Dr. Davies was a most conscientious worker, held high ideals of professional duties and responsibilities, and never thought any sacrifice too great for the sake of his patients. No doctor was held in higher esteem for his skill and devoted services. To his fellow practitioners he was loyal and helpful, and was frequently called by them into consultation.

Dr. Davies took a deep interest in medical politics. He acted as secretary to the South-West Wales Division of the British Medical Association for many years, and was its first representative at the Annual Meetings of the Association. He took an active part in the work of the Carmarthen Panel Committee, was a member of the Insurance Acts Committee of the British Medical Association, and for some time of the National Health Advisory Committee. All this committee work—in addition to the duties of a large practice—was done by one never in robust health and is an indication of the energy and enthusiasm he devoted to his profession. Dr. Davies was a staunch temperance advocate and was a devout and sincerely religious man. He held the office of deacon of the English Presbyterian Church, Llanelli.

We regret to record the death at Lewes, Sussex, on August 10th, of Dr. JOHN ROBERT STENHOUSE, aged 52 years. Dr. Stenhouse received his medical education at Guy's Hospital, and took the diplomas of a B.R.C.S.Eng. and L.R.C.P.Lond. in 1894; he graduated M.B., B.S.Lond. in 1895 and M.D. (qualified for gold medal) in 1907; in 1904 he took the D.P.H. He held the posts of resident obstetrician and house-surgeon at Guy's Hospital, and clinical assistant at the Royal Ophthalmic Hospital, Southwark. Dr. Stenhouse started practice in Lewes in 1897, and was honorary surgeon to the Victoria Hospital there. At the height of his success when the war broke

out, and as a surgeon lieutenant in the Sussex Yeomanry he was mobilized early in August, 1914. He never returned to his home until he came back from France in 1918, shattered in mind and body. In Lewes, where he was medical officer of health and school medical officer, he will long be remembered for his work in the prevention of infantile mortality, and for the object-lesson he set on the treatment of pulmonary tuberculosis in his private sanatorium on the Downs. As a physician he was remarkable for his accuracy in diagnosis and for the unremitting care he bestowed on his patients. Among his fellow officers in the war he will be remembered particularly for his gallantry and devotion on the night of the heaviest raid at Etaples in May, 1918, when he organized and led a body of volunteers, who rescued many men from burning huts when rescue seemed impossible and official attempts at it had ceased. Stenhouse was known also as an athlete and keen sportsman; in his student days he won trophies at Guy's. He was a member of the Lewes Priory Cricket Club and of the Southdown Hunt. He leaves a widow, two sons, and a married daughter.

We regret to record the death, on June 28th, of Dr. HERMANN MICHAEL BIGGS, State Commissioner of Health for New York, at the age of 63. He received his medical education at Bellevue Hospital Medical College, and qualified in 1883. In 1885 he was appointed professor of pathological anatomy at his college, in 1897 professor of therapeutics and clinical medicine, and in 1914 professor of medicine. He was director of the bacteriological laboratories of the New York Department of Health from 1892 to 1901, and general medical officer from 1901 to 1911, when he was appointed State Commissioner of Health. He had been a director of the Rockefeller Institute of Medical Research since its organization in 1901. Dr. Biggs was a member of the British Medical Association, and a Fellow of the New York Academy of Medicine. At the Annual Meeting of the British Medical Association held at Montreal in 1897 he delivered the address in public medicine, taking as his subject "Preventive medicine in the City of New York." In this he discussed some of the measures more particularly distinguishing the work of his department and described some of the procedures followed in the sanitary surveillance of infectious diseases which had been introduced by it. He took the occasion to pay a warm tribute to the leading part taken by England in the matter of public health. The address was printed in full in the BRITISH MEDICAL JOURNAL of September 11th, 1897 (p. 629). During the war he was nominated as a member of many important American committees in connexion with war organizations, and he was medical director of the League of Red Cross Societies at Geneva in 1920. His name will long be remembered for his pioneer work in the establishment of municipal bacteriological laboratories.

Dr. EDWARD R. HOLBOROW of Weston-super-Mare lost his life on August 18th in endeavouring to rescue two school girls who had got into difficulties while bathing in a rough sea. He had dived into the water fully dressed. Dr. Holborow, who was only 37 years of age, received his medical education at the University College, Bristol, and University College, London, and graduated M.B., B.S.Lond. in 1909. College, London, and graduated M.B., B.S.Lond. in 1909. After taking the diploma of F.R.C.S.Eng. in 1917. Before settling at Weston-super-Mare he had served as house-surgeon to the Cardiff Infirmary, the Somerset Hospital, Cape Town, and the Pretoria Hospital, Transvaal. He served at Gallipoli during the war. He is survived by a widow and two young children, with whom deep sympathy is felt.

Dr. WILLIAM STUART ARMITAGE died at Pembroke on July 31st, aged 55. In early life he served for a short time in the Royal Artillery, and held a commission as lieutenant in the Reserve (R.F.A.) from July 21st, 1886. As such he served in West Africa in 1893. After going through the medical curriculum at St. George's, he took the diplomas of M.R.C.S.Eng. and L.R.C.P.Lond. in 1913, at the age of 45. During the recent war he rejoined the Royal Artillery as lieutenant on August 29th, 1914, and was subsequently promoted to captain.

SCROLLS.

Most colleges grant scholarships open to intending medical students for £50 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges, from the principles of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.A. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize and the (including Anatomy, Physiology, and Pathology) of £20 for one year, open to the University, is awarded annually by the Master and Fellows of University College. A Burney Xeo Kings' College Hospital Scholarship of £50 is awarded annually.

5333

an annual fee of £1 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are: the B.A., £7 10s.; the B.L. and B.C.H., £1; the D.L., £23; the D.L.C., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £51 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £180, or for women not less than £140.

For further information application may be made to Dr. E. W. Amler, Walker, Dean of the School of Medicine, University of Oxford.

## UNIVERSITY OF CAMBRIDGE.

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Ch.), each of which entitles the possessor to admission to the Register by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also awards diplomas in "Medical Medicine" and "Public Health."

and foreign diplomats in tropical medicine, in Public Health, and in Medical Radiology and Electrophysiology. Information regarding these diplomats will be found in later sections under the headings Tropical Medicine, Public Health, and Radiology. A candidate for the

M.B., B.Ch degrees need not possess a degree in arts ; it is sufficient if he has passed the previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Sciences, Tripos at the end of their third year. Under the new regulations

the attainment of a sufficient standard in chemistry or physiology in this Tripos will secure exemption from the corresponding tests in the second M.B. examination. Women students, members of Girton or Newnham College, are now admitted, under certain conditions, to the first and second M.B. examinations.

into force in October, 1923.

First M.B.—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the previous

examination and paid the matriculation fee. Certain exemptions from the first M.B. examination are allowed; the regulations may be obtained from the Registrar. The complete examination is held twice a year—in October and June; an additional examination, in parts 2 and 4, is held in December.

*Second, M.B.*—This examination, which cannot be passed

Part I, organic chemistry; Part II, human anatomy and physiology; Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of pathology. No one may enter Part III unless he has passed Parts I and II. The candidate must be signed up in all three subjects and have dissected for one academic year. The examination for Parts I and II is held in December and January, that for Part III in October and April.

kind of thing. This is divided into two parts, to neither of which is the candidate admitted until he has passed the examination on general medicine mentioned above. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology), must have completed five years of medical study and practice, and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of study.

hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physic (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine), and pharmacology (including therapeutics and toxicology). The third M.B. examinations are held twice a year—in June and December.

*Act for the M.B.*—Before receiving his M.B. degree a candidate who has been successful at the final M.B. examinations has to write a thesis. "This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Regius Professor of Physic a dissertation, which is laid before the Degree Committee.

The M.D. degree may be taken by a bachelor of medicine after three years' standing after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology or therapeutics) is chosen.

The M.Ch. degree may be granted to a candidate who has qualified for the B.Ch. at least two years previously; he is then examined in pathology, surgery, surgical anatomy, and

extempore essay. The tests are partly practical: they include the writing of an surgical operations. The tests are partly in writing, partly

to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registrar, Cambridge.

degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should secure and carefully study the booklets relating to it.

The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days; the first two take place both in London and in certain provincial centres; the September examination is held in London only. In no circumstances is a degree granted to anyone in less

than three years after the date at which he passed the

water. Intradural injection of 1 c.cm. of (25 per cent.) solution per kilo of body weight produces temporarily after three or four hours all the symptoms of section of the cord, and may give rise to respiratory disturbance, paralysis of sphincters, and especially to retention of urine. The authors have experimented with solutions of magnesium citrate and chloride, in addition to the sulphate; solution of magnesium citrate produces perfect analgesia which lasts longer than that produced by the other salts. The technique is very simple: they inject 10 c.cm. of the 25 per cent. solution—4 c.cm. by the epidural route and 2 or 3 c.cm. into the various painful points in the course of the sciatic nerve. They prefer the epidural route as yielding equally good results without the dangers of the intradural method. The results are as follows: The sedative action commences after a period of one and a half to three hours and is more marked the next day; the relief obtained usually persists longer in acute than in chronic cases—in the former it frequently lasts for four days, but in the latter it has not persisted for more than two or three days. In one case relief was not obtained after the injection of 15 to 20 c.cm. No symptoms of intolerance were observed, but chemically pure salts must be used, otherwise the injections may produce pain. Details of the 10 cases are given.

#### 143. Prophylaxis of Mumps Orchitis.

A. CHALLAMEL (*Bull. Soc. de Théor.*, May 9th, 1923, p. 116), whose previous communication on the prophylaxis of mumps was recently noticed (EPITOME, June 9th, No. 471), has lately employed colloidal silver, owing to its bactericidal properties, as a prophylactic against orchitis in mumps. The drug was given by mouth, in doses of 12 to 16 cg. a day, in the form of pills or cachets taken three or four times daily. In none of the fifteen cases of mumps in which this method was employed did orchitis occur, whereas in Challamel's previous experience one out of every three or four cases of mumps developed this complication.

## Surgery.

#### 144. Acute Osteomyelitis of the Patella.

H. L. ROCHER (*Paris Méd.*, July 21st, 1923, p. 74), who has collected 50 cases, including one of his own in a boy aged 13, states that osteomyelitis of the patella is an affection which occurs chiefly between the ages of 5 and 15, and is most frequent in boys. It usually runs its course without affecting the joint, but in exceptional cases, as in that reported by Rocher, the joint may be involved from the first or may be affected secondarily. The acute extra-articular form has the appearance of a prepatellar abscess, and is usually accompanied by an aseptic hydrarthrosis. A sinus may be caused by a partial or complete necrosis of the patella or by a small area of fungating osteitis. A few cases of chronic or prolonged osteomyelitis have been observed. The acute intra-articular form resembles suppurative arthritis of the knee, and the origin of the suppuration in the joint can only be determined by a profile x-ray picture. Treatment consists in incision, scraping the lesion in the bone, removal of one or more sequestra, and complete excision of the patella if the lesions are diffuse. Regeneration of the patella can only be expected if the fibro-periosteal covering and the deep layer of cartilage protecting the joint cavity are preserved. In the form of osteomyelitis in which the joint is involved from the first, removal of the patella by the anterior route, completed by lateral arthrotomy or a counter-incision in the cul-de-sac beneath the quadriceps, is indicated. In osteomyelitis complicated secondarily by infection of the joint the local lesion should be treated and the joint drained and immobilized. Amputation is only needed in the presence of severe septicaemia.

#### 145. Tuberculosis of the Tongue.

FANTOZZI (*Il Policlinico*, May 15th, 1923, p. 234) publishes a case of primary tuberculosis of the tongue. Lingual tuberculosis is a rare disease, especially when the numerous opportunities of infection which occur are borne in mind. This immunity is chiefly due to the muscular structure of the tongue. Primary localizations are extremely rare. Clinically the cases may be divided into a lupous type, an ulcerative or superficial type, and a nodular or interstitial type. Diagnosis is often difficult, and bacterioscopic and histological examination of a portion of the growth is most important. As far as the actual local affection is concerned the prognosis is good, but one always has to bear in mind possible tuberculous disease in other organs of the body. The ulcerating and nodular types should be excised, and in every case general antituberculous treatment should be administered. In cases not favourable for excision x rays or Finsen light may be used.

#### 146.

#### Lymphangitic Abscess of the Neck.

P. CLAIRMONT (*Schweiz. med. Woch.*, May 3rd, 1923, p. 441) points out that surgical textbooks usually trace abscesses in the lower part of the front of the neck to inflammation of the thyroid gland. He has come to the conclusion that in many cases the abscess in this position is caused by suppuration in the lymphatic vessels running deep to the mid-fascia of the neck in the triangular space bounded by the middle line, the main blood vessels of the neck as they run under the sterno-mastoid muscle, and above by the median portion of the omo-hyoid muscle, from the point where it crosses the jugular vein to the middle line. The author records in detail three cases of lymphangitic abscess in this triangle. In every case suppurative thyroiditis was suspected or actually diagnosed before the operation, which showed a well defined abscess cavity just under the mid-cervical fascia. A microscopic examination of the wall of the abscess cavity in one of these cases showed it to consist of granulation tissue, and the pus found contained the *Streptococcus pyogenes* in one case, and a Gram-negative bacillus belonging to the lactic acid bacillus group in another case. No bacteriological examination was made in the third case. The prognosis is good for this form of abscess, and after evacuation of the pus uneventful recovery usually occurs. The course of the disease is, in fact, that of lymphangitic abscesses in the limbs, and the chief interest attaching to the lymphangitic abscess described by the author lies in the fact that it has hitherto seldom, if ever, been identified as a simple lymphangitic abscess with well defined boundaries. It must not, as has sometimes happened, be confused with diffuse phlegmon of the neck.

#### 147. Treatment of Rupture of the Achilles Tendon.

H. ABRAHAMSEN (*Ugeskrift for Læger*, April 26th, 1923, p. 279) considers that subcutaneous rupture of the Achilles tendon from violent straining is more often complete than incomplete, and that only when it is incomplete is conservative treatment justifiable. As it is difficult to distinguish between the two simply by palpation, he prefers operative treatment in most cases. Without operative treatment it is impossible to ascertain the extent and nature of the lesion, and the torn ends may be so far apart, and the strands of tendon may be so torn, frayed, and retracted, that the prospect of firm and early union without excessive lengthening of the tendon is almost negligible. The surgeon who relies on conservative treatment only cannot be sure that these obstacles to rapid and complete recovery are absent unless he operates. To enforce his arguments in favour of operative treatment, the author records in detail 7 cases, in 4 of which the original diagnosis of incomplete rupture proved to be mistaken. In 2 cases the diagnosis of partial rupture led to conservative treatment with massage, but a year later there was still almost complete loss of function. In 2 other cases union had, indeed, occurred, but the functions of the tendon were greatly impaired by its increased length. The author believes that other surgeons have also of late become more and more convinced of the superiority of operative over conservative treatment in most cases.

#### 148. Albee's Operation for Pott's Disease.

F. LANGENSKIÖLD (*Finska Läkarsällskapets Handlingar*, May-June, 1923, p. 237) warmly recommends Albee's operation as the usual method of treatment for Pott's disease in adults, provided there is no severe and permanent kyphosis, and the disease is not situated in the cervical vertebrae. At this level the prognosis for the disease is comparatively good, and it is seldom, if ever, necessary to operate. Spinal abscesses should be treated by the usual methods before the operation is undertaken, and an attempt should be made to relieve paralysis before operating. Fistulae are no contra-indication, and slight forms of pulmonary tuberculosis are operation, and slight forms of pulmonary tuberculosis are also no contra-indication. These views are founded on the author's experience of 34 cases, only 7 of which were operated on under ether anaesthesia. In the remaining cases local anaesthesia was employed, and it is certainly to be preferred to general anaesthesia. It is undesirable to supplement the operation by plaster supports and other apparatus which make sun and open-air treatment unnecessarily difficult for the patient's home. He should be advised not to work for six months after the operation. In 3 of the author's 34 cases the observation period was too short for conclusions to be drawn as to the results. Among the remaining cases there were 20 which were observed for half a year to two and a half years after the operation, and which showed complete clinical recovery and fitness for work. Among the 11 remaining cases there were 3 terminating fatally from myeloid disease. Only in 2 cases did the bone grafts fail to immobilize the spine as completely as was intended.

The fee for matriculation is £2, £2 10s. for pre-medical examination (if taken in university), and £2 10s. for each of the first four professional examinations; M.B., Ch.B., degrees fee, £10; M.D. and Ch.M. examinations, £12 10s. each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

# UNIVERSITY OF BRISTOL.

The university grants the following degrees: In medicine and surgery, M.B., Ch.B., M.D., Ch.M. (the M.D. may be taken in State medicine); in dental surgery, B.D.S., M.D.S. (Diplomas in public health (D.P.H.) and dental surgery (D.S.) are also granted. Candidates for degrees must qualify for matriculation in the university by passing either one of the school certificate examinations held twice a year in July and in September by the university itself, or the Higher School Certificate, or any one out of a list of similar examinations which will be found in the university regulations for matriculation. Candidates over the age of 28 may, in certain circumstances, be permitted to matriculate without examination. The winter session opens on October 2nd, 1923.

Candidates who possess a Higher School Certificate approved by the Board of Education in physics, chemistry, and biology may count the first year of the curriculum and the first examination—the curriculum being thus reduced to four and a half years in the university.

## PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are three examinations for these degrees. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The first M.B. second M.B. comprises organic chemistry, elementary anatomy (Part I), advanced anatomy, physiology (Part II), pharmacology, and therapeutics, general pathology, morbid anatomy, and bacteriology (Part II), special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical and operative), medicine (systematic, clinical, and practical), including mental diseases (Part II). The two groups may be taken separately or together. At the option of the candidate, forensic medicine and toxicology may be taken either with Group I or Group II. First or second class honours may be obtained by a candidate whose work is deemed of sufficient merit, but cannot be awarded to one who has recorded against him a failure at any examination after the first M.B.

M.D.—A candidate must be a M.B. and Ch.B. of at least two years' standing. He has a choice between presenting an original dissertation, undergoing a general examination in medicine (including medical anatomy, medical pathology and bacteriology, systematic and clinical medicine), or passing an examination in State medicine.

Ch.M.—A candidate must have attended, since becoming M.B., Ch.B., and for not less than two years, a public institution affording opportunities for the study of practical surgery, and produce certificates to that effect; the candidate shall be required to pass a general examination in surgery (including surgical anatomy, surgical pathology and bacteriology), operative and clinical surgery, and to present a dissertation in some department of surgery. He must be awarded after examination in general surgery and in special subjects—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

Applications for other information should be addressed to the Dean of the Medical Faculty.

## UNIVERSITY OF DURHAM.

To its own graduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and Doctor of Medicine (M.D.), and Master of Surgery and Doctor of Surgery (M.S., D.Ch.); it also grants special degrees and diplomas in Public Health, Psychiatry, and Dental Surgery. To become

a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts, or even to commence that period by matriculation. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, Newcastle-on-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere, but not less than a year must elapse between the date when the student satisfies the requirements of the university as regards matriculation and his presenting himself for the Final M.B., B.S. Examination.

The university has its own matriculation examination, but accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application.

## PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. Each is held twice a year—in March and June. The first deals with elementary anatomy and biology, chemistry and physics; the second with anatomy and physiology; the third with pathology, elementary bacteriology, medical jurisprudence, public health, materia medica, and pharmacy. At the final M.B., B.S., the candidate is examined in medicine and clinical and psychological medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical gynaecology; therapeutics; diseases of the throat, nose, and ear; diseases of the skin; and diseases of the eye.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not a M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 353.)
